A Brief History of MapReduce

General Batch Processing

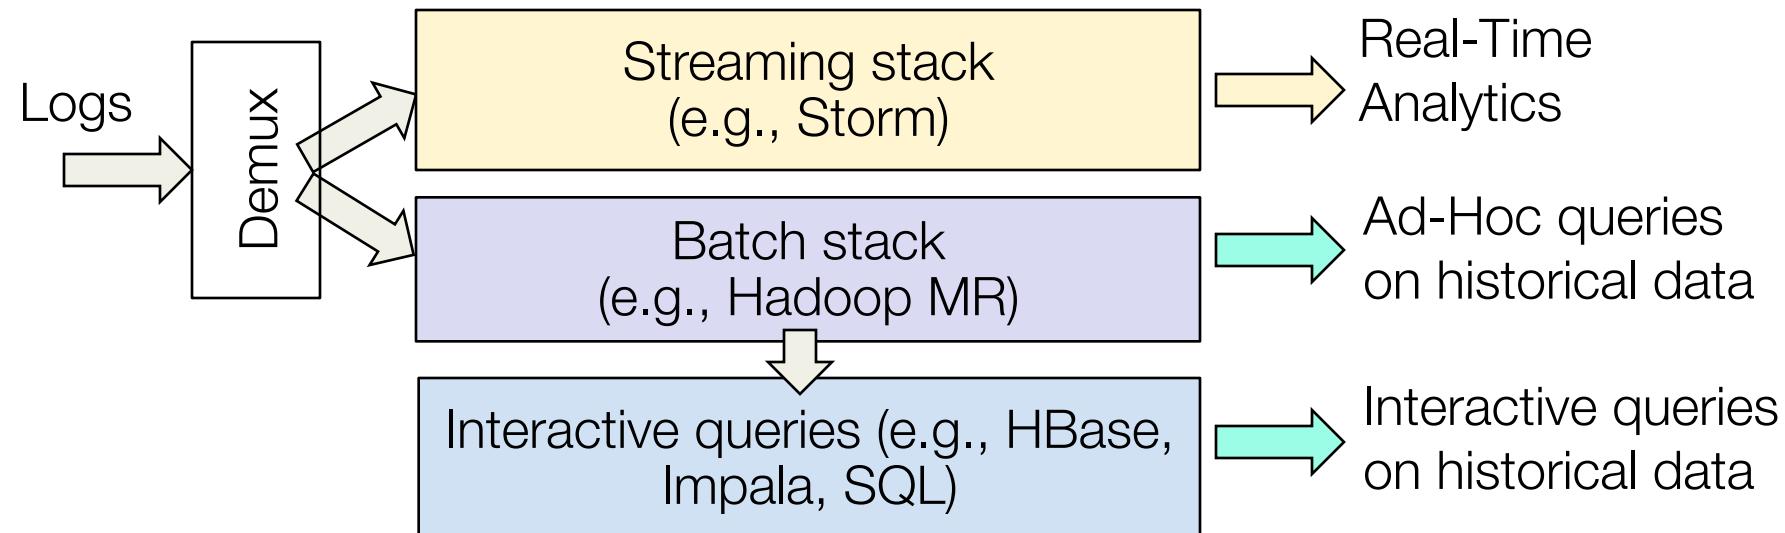

Specialized Systems:

iterative, interactive, streaming, graph, etc.

MR doesn't compose well for large applications,
and so *specialized systems* emerged as workarounds

The Need for Unification (1/2)

■ Big Data Analytics stack BEFORE Spark/BDAS

Challenges:

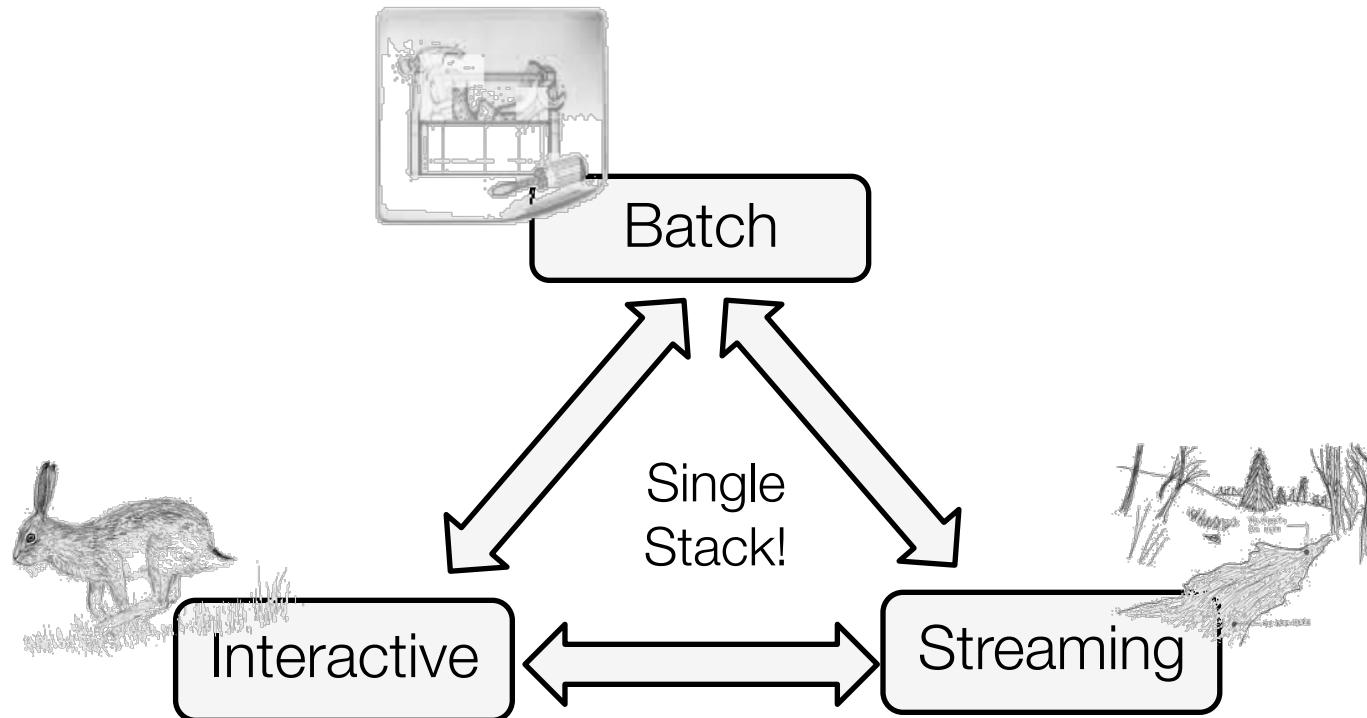

- » Need to maintain three separate stacks
 - Expensive and complex
 - Hard to compute consistent metrics across stacks
- » Hard and slow to share data across stacks

The Need for Unification (2/2)

- Make real-time decisions
 - Detect DDoS, Fraud, etc
- E.g.,: what's needed to detect a DDoS attack?
 1. Detect attack pattern in real time → streaming
 2. Is traffic surge expected? → interactive queries
 3. Making queries fast → pre-computation (batch)
- And need to implement complex algos (e.g., ML)!

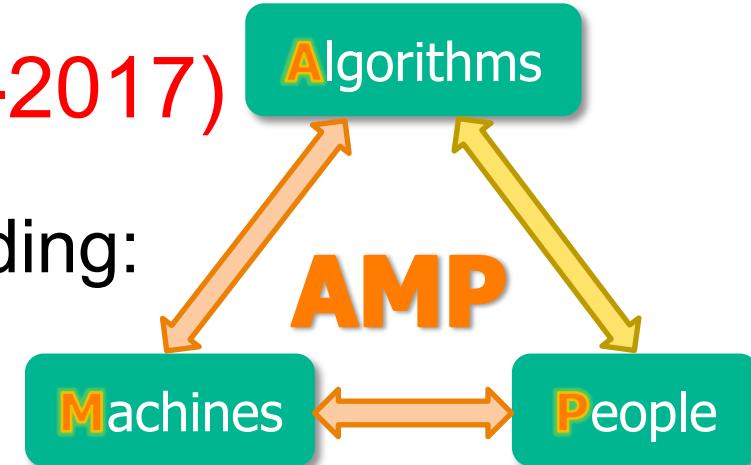

Goal of the Berkeley Data Analytics Stack (BDAS) Project by AMPLab @ UCB

- Support *batch*, *streaming*, and *interactive* computations...
... and make it easy to compose them
- *Easy* to develop *sophisticated* algorithms (e.g., graph, ML algos)

The Berkeley AMPLab (2011-2017)

- Governmental & industrial funding:

Goal: Next generation of open source data analytics stack for industry & academia:
Berkeley Data Analytics Stack (BDAS)

Data Processing Stack

Data Processing Layer

Resource Management Layer

Storage Layer

Hadoop Stack

Hive

Pig

HBase

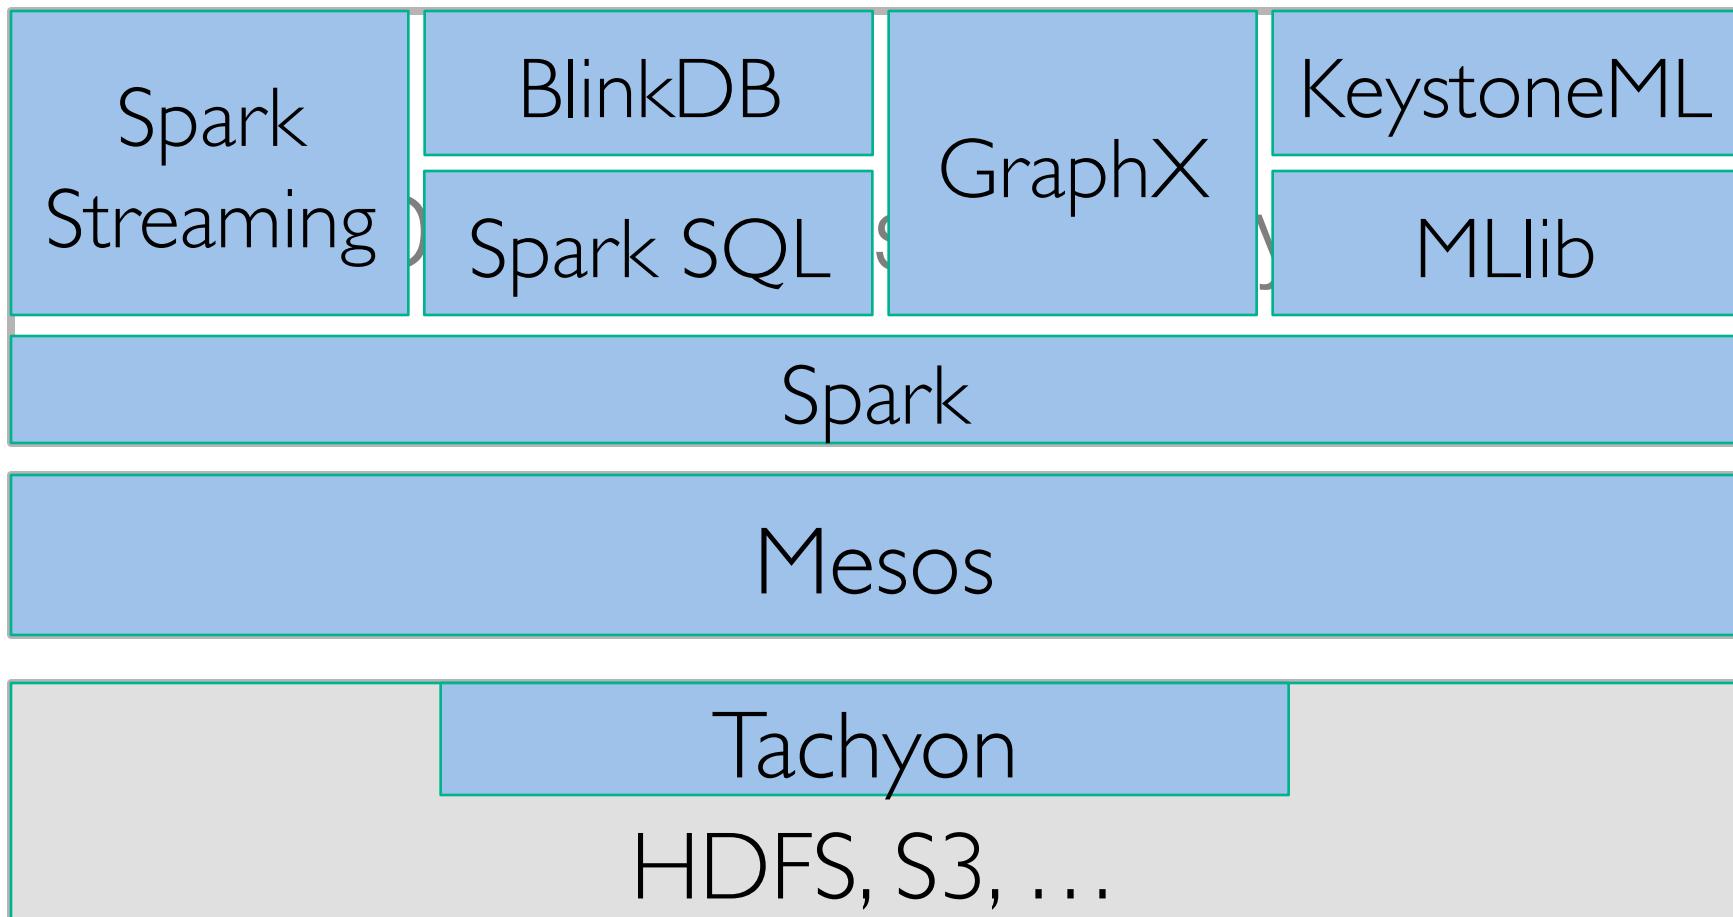

Storm

Hadoop MR

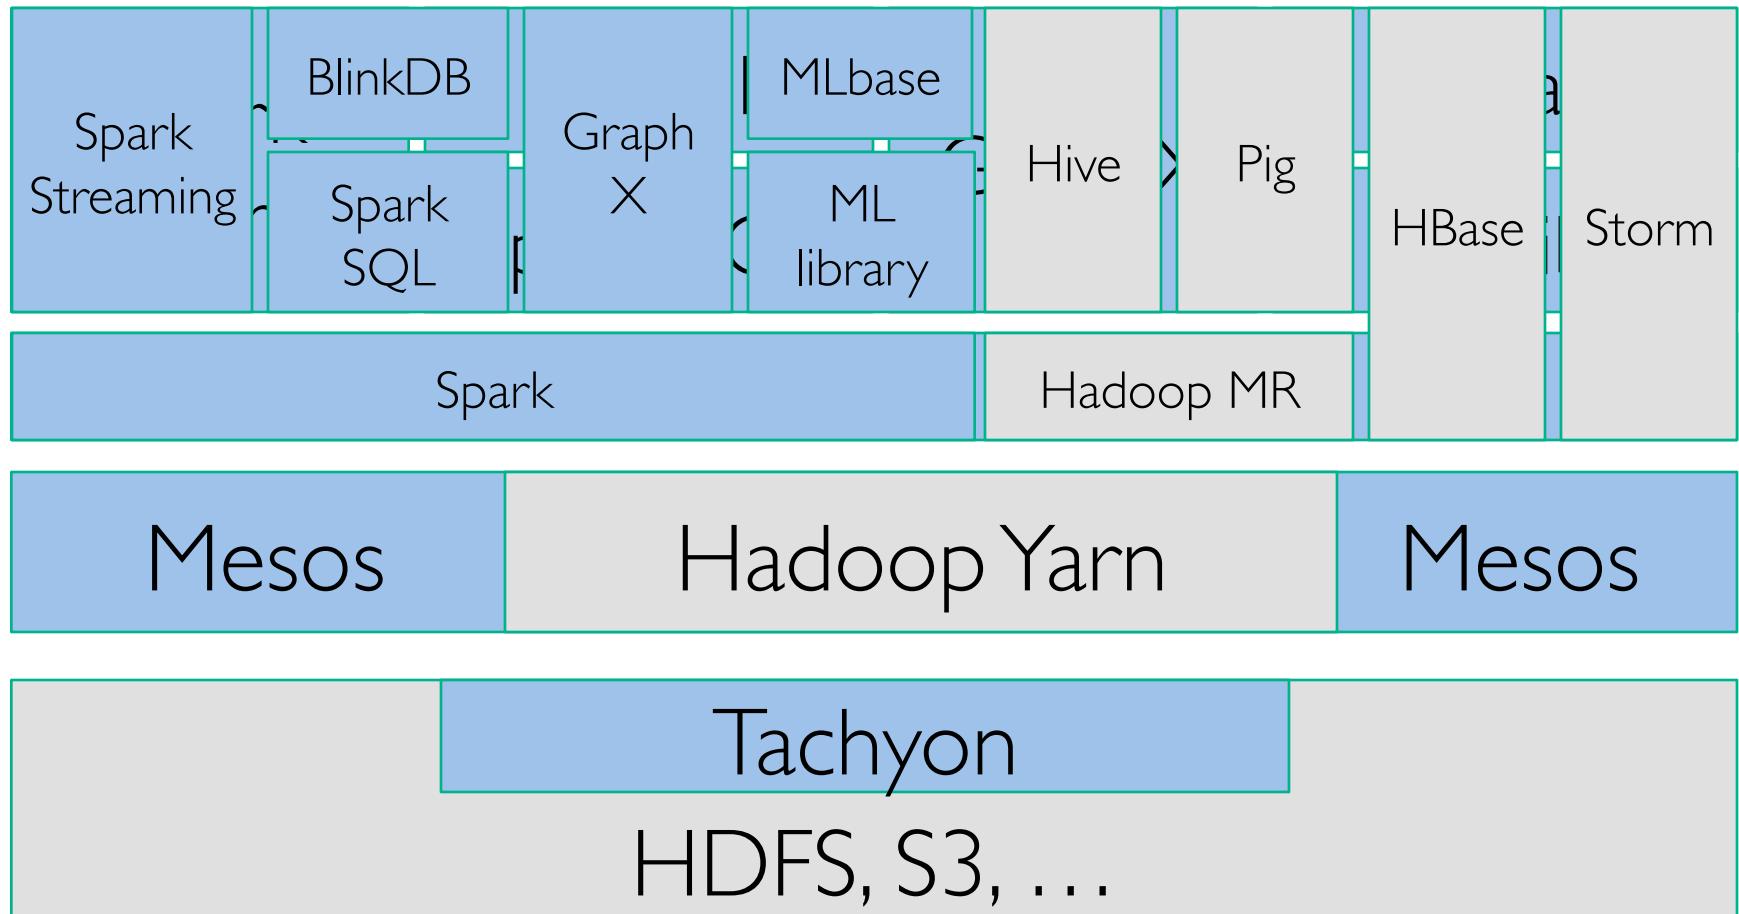

Hadoop YARN

HDFS, S3, ...

BDAS

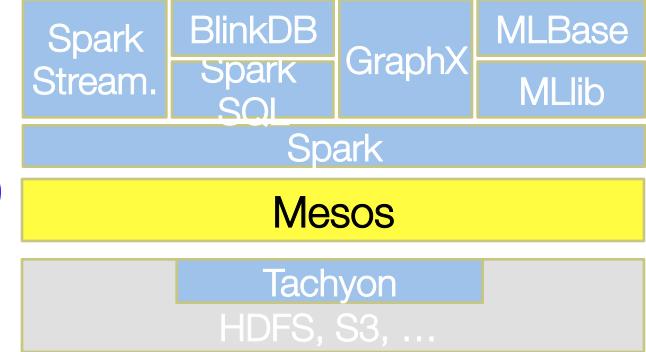

How do BDAS & Hadoop fit together?

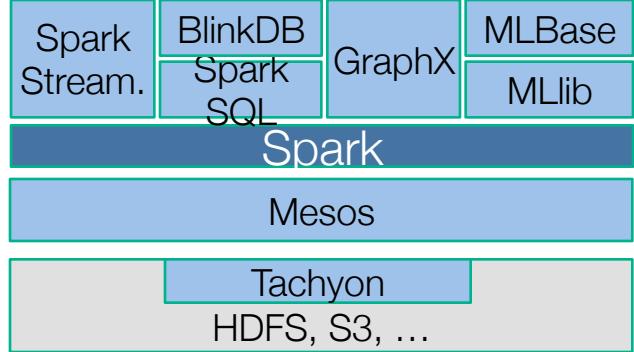

Apache Mesos

(<http://mesos.apache.org>)

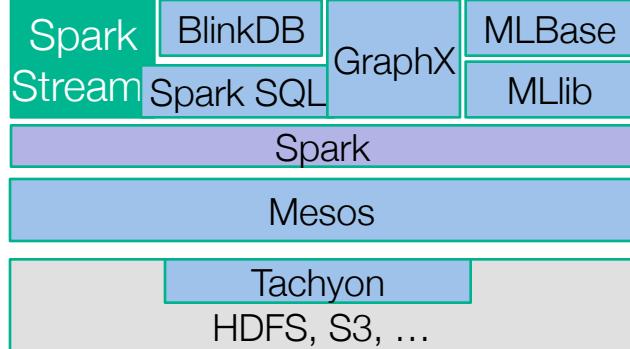

- Another competing Cluster Resource Management software
- Enable multiple frameworks to share same cluster resources (e.g., MapReduce, Storm, Spark, HBase, etc)
- Originated from UC Berkeley's BDAS project ;
 - B. Hindman et al, "Mesos: A Platform for Fine-Grained Resource Sharing in the Data Center", Usenix NSDI 2011.
- Hardened via Twitter's large scale in-house deployment
 - 6,000+ servers,
 - 500+ engineers running jobs on Mesos
- Third party Mesos schedulers
 - AirBnB's Chronos ; Twitter's Aurora
- Mesosphere: startup to commercialize Mesos

Apache Spark

- **Distributed Execution Engine**
 - Fault-tolerant, efficient in-memory storage (RDDs)
 - Powerful programming model and APIs (Scala, Python, Java)
- **Fast:** up to 100x faster than Hadoop
- **Easy to use:** 5-10x less code than Hadoop
- **General:** support interactive & iterative apps

Spark Streaming

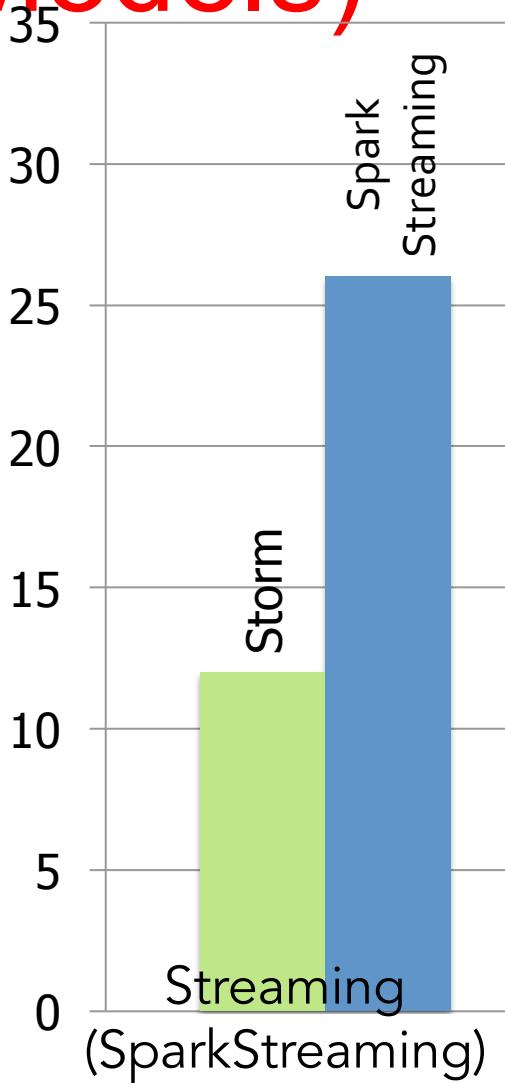

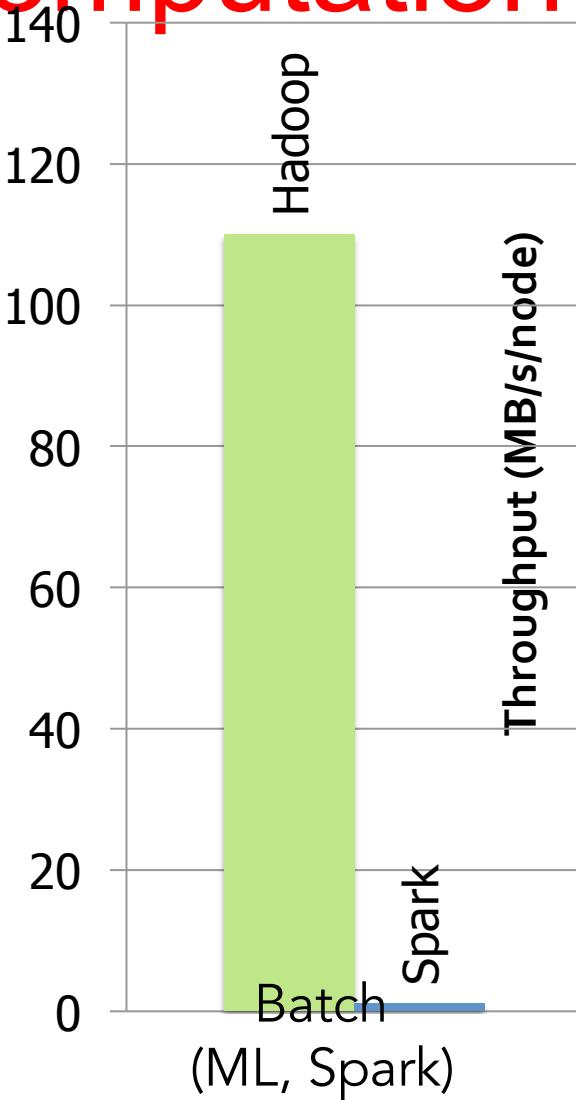

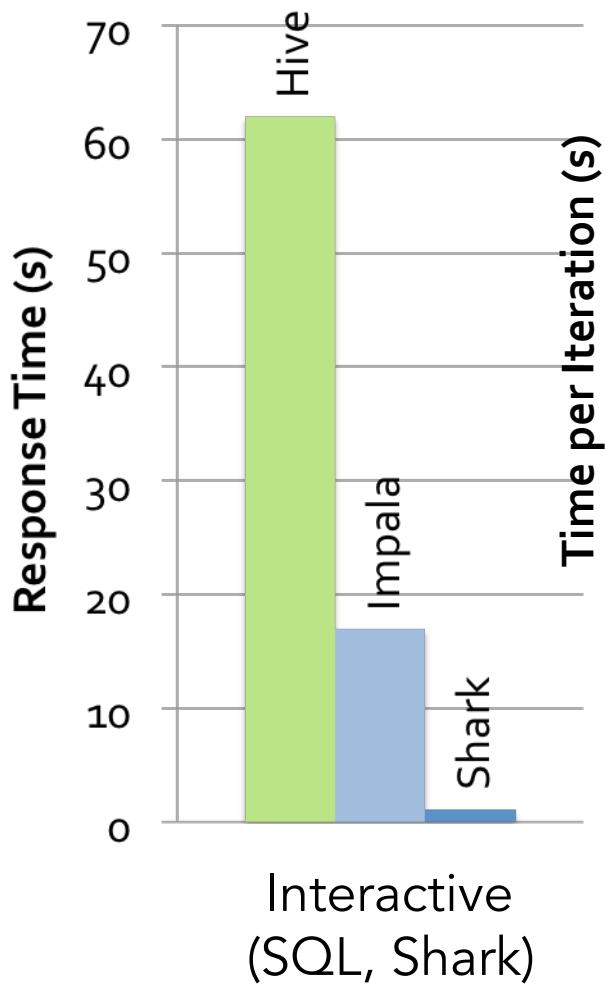

- Large scale streaming computation
- Implement streaming as a sequence of <1s jobs
 - Fault tolerant
 - Handle stragglers
 - Ensure “exactly once” semantics
- Integrated with Spark: unifies **batch**, **interactive**, and **batch** computations

Unified Programming Models

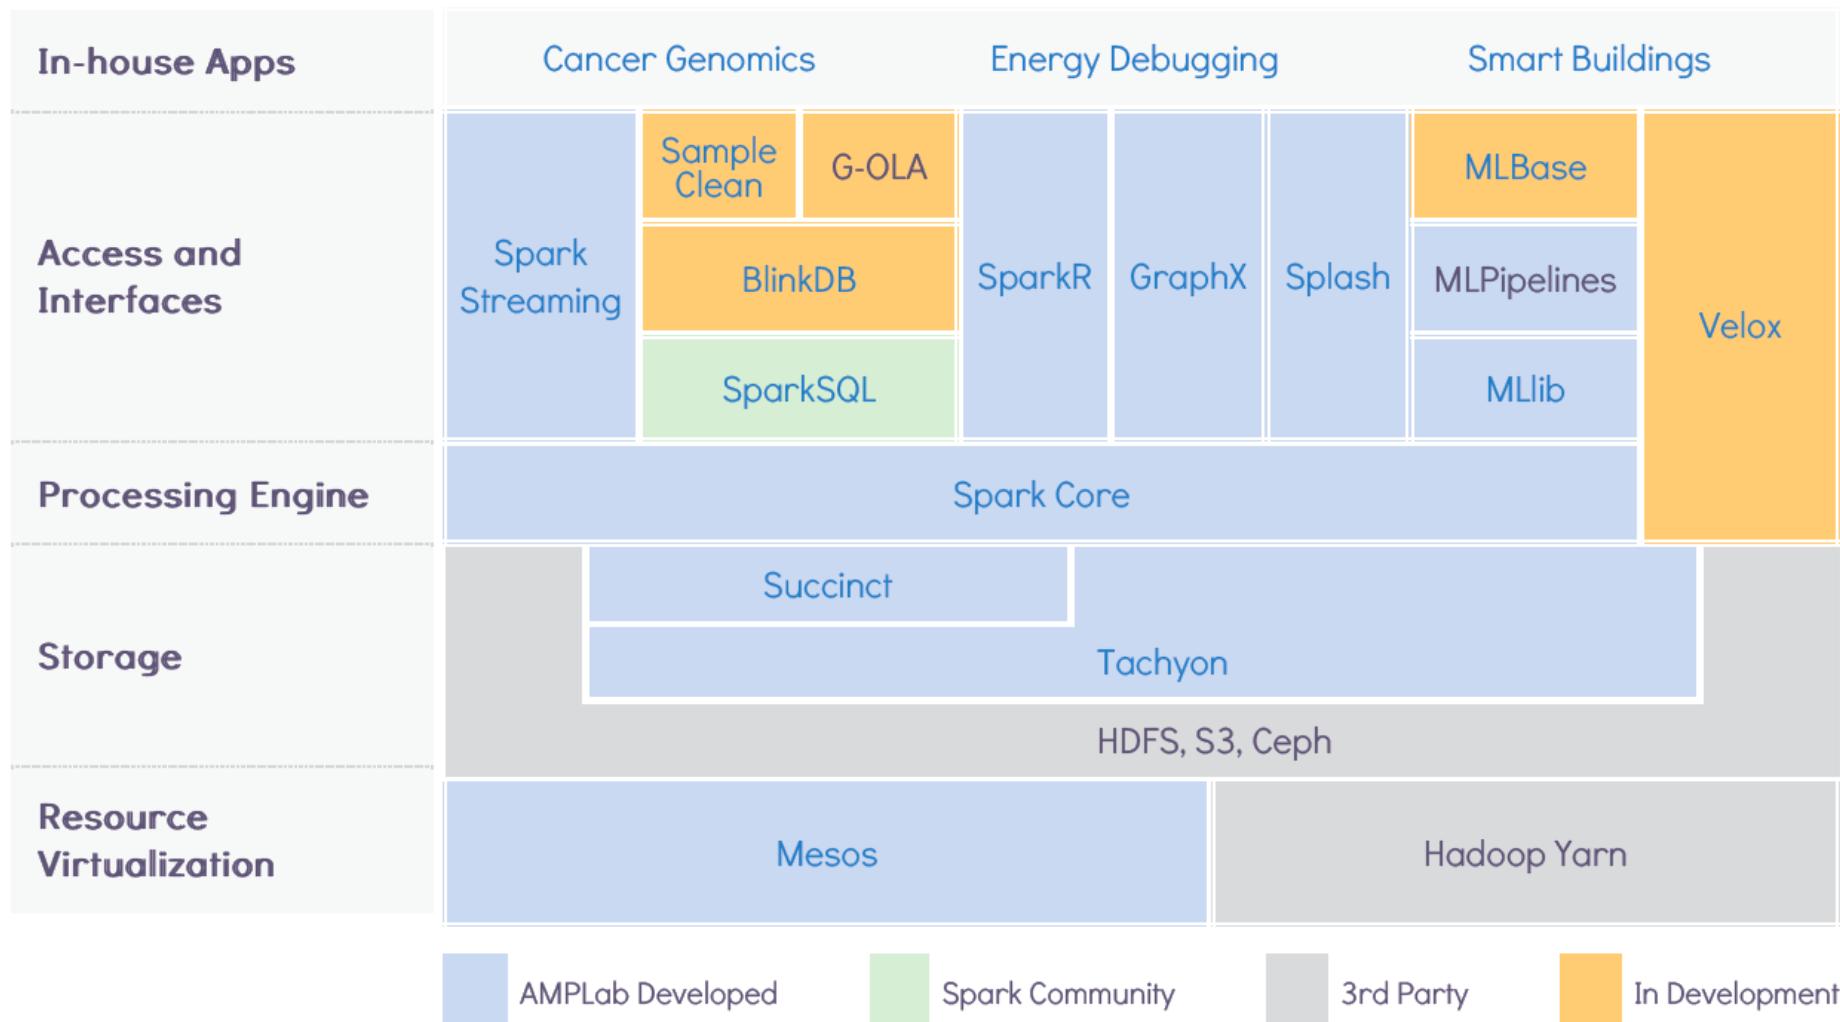

- Unified system for SQL, graph processing, machine learning

```
def logRegress(points: RDD[Point]): Vector {  
    var w = Vector(D, _ => 2 * rand.nextDouble - 1)  
    for (i <- 1 to ITERATIONS) {  
        val gradient = points.map { p =>  
            val denom = 1 + exp(-p.y * (w dot p.x))  
            (1 / denom - 1) * p.y * p.x  
        }.reduce(_ + _)  
        w -= gradient  
    }  
    w  
}  
  
val users = sql2rdd("SELECT * FROM user u  
    JOIN comment c ON c.uid=u.uid")  
  
val features = users.mapRows { row =>  
    new Vector(extractFeature1(row.getInt("age")),  
               extractFeature2(row.getStr("country")),  
               ...)}  
val trainedVector = logRegress(features.cache())
```

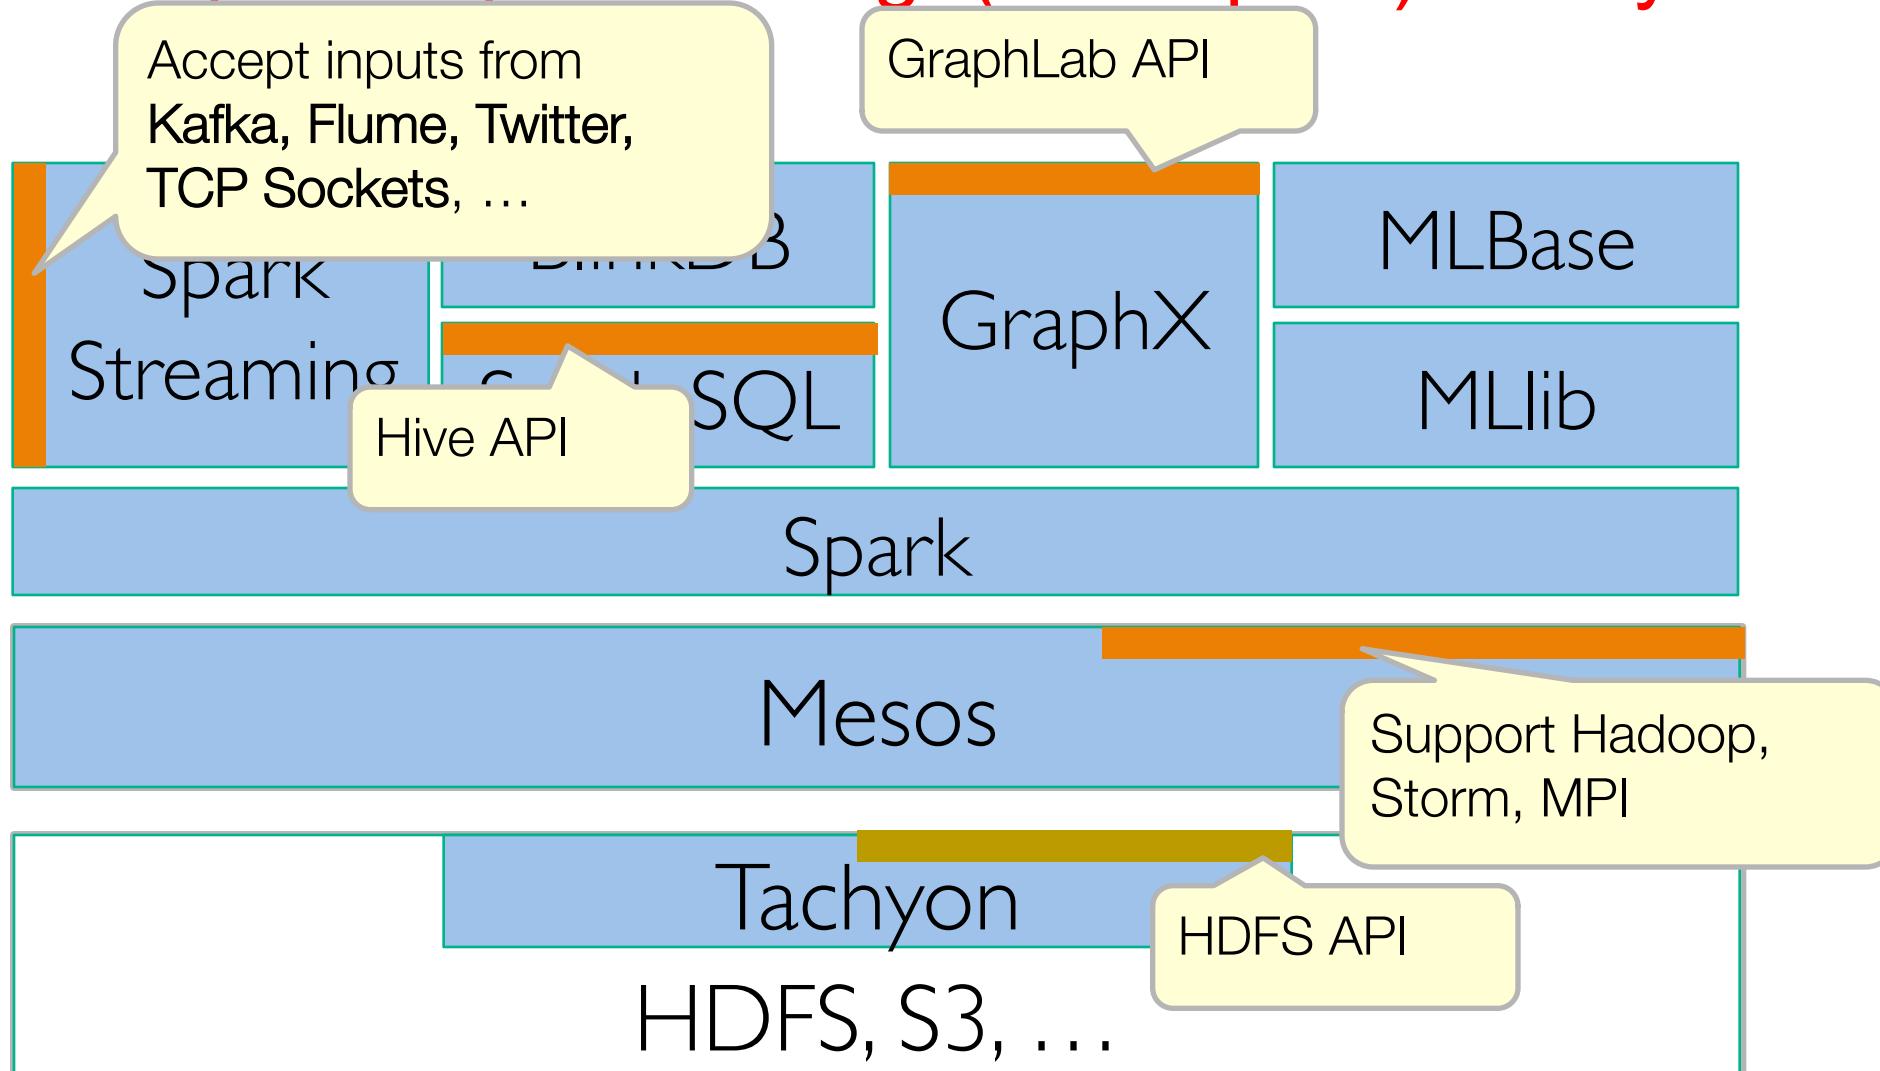

Performance and Generality (Unified Computation Models)

BDAS (as of late 2015)

Compatibility to existing (non-Spark) Ecosystem

Highly Visible Industrial Impact

Thousands of companies using BDAS components

Three startups behind BDAS main components

Mesos  MESOSPHERE

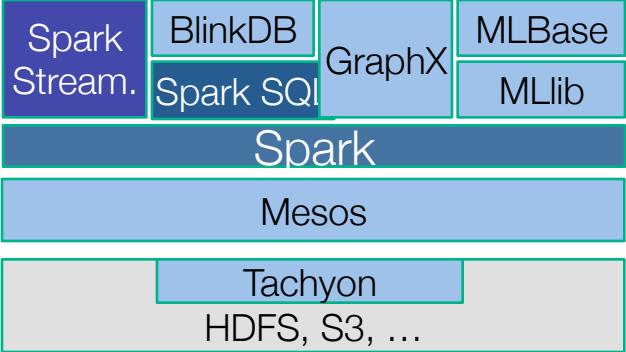

Spark  databricks

Tachyon  TACHYON Recently renamed to:

 ALLUXIO

Rapid Adoption

- Train > 10K people via Tutorials in AMPCamp 1-6, Strata, Spark Summits and MOOCs
- 42K+ Spark Meetup members
- 600+ Contributing Developers to codebase

Highly Visible Industrial Impact – Large Scale Usage

Largest cluster: 8000 nodes **Tencent** 腾讯

Largest single job: 1 petabyte **Alibaba** 阿里巴巴   databricks

Top streaming intake: 1 TB/hour 

2014 on-disk sort record

Spark Ecosystems

Distributions

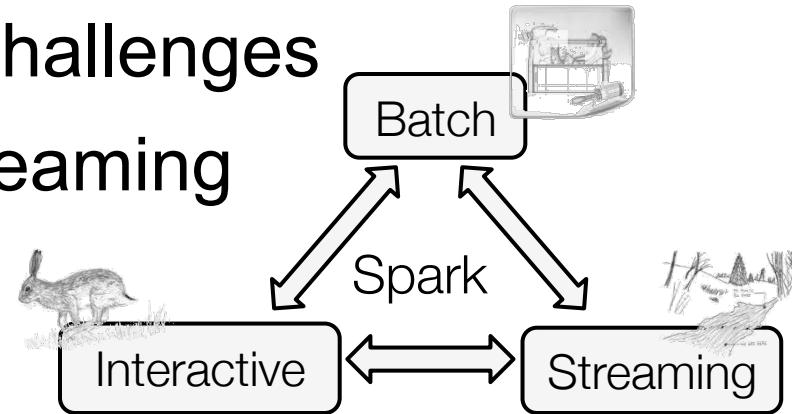

Applications

BDAS Summary

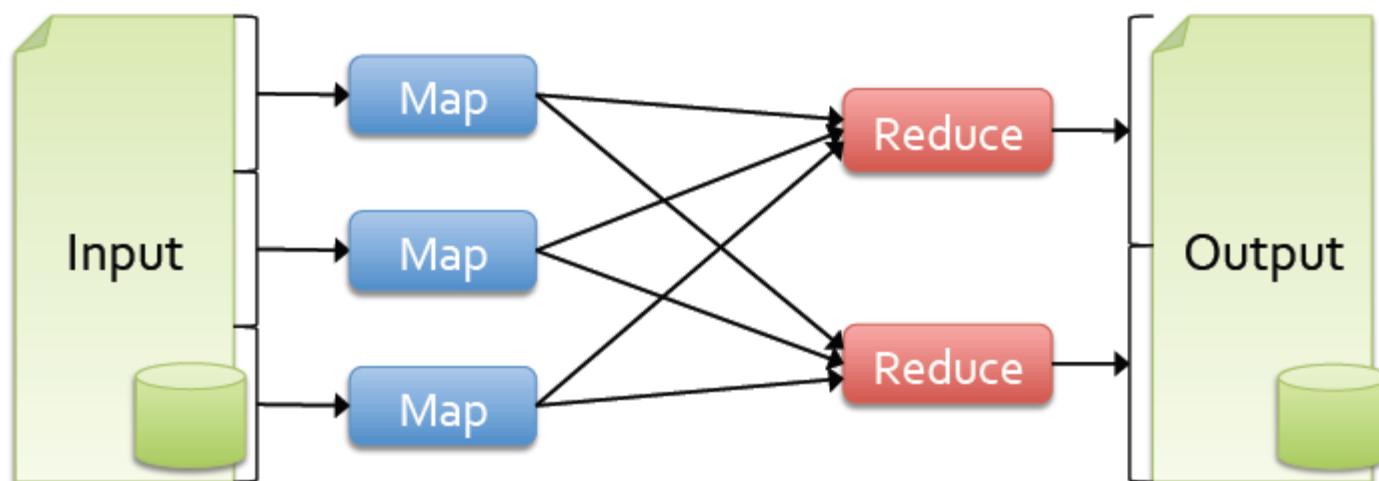

- BDAS: address next Big Data challenges
- Unify batch, interactive, and streaming computations
- Facilitate the development of sophisticated applications
 - Support graph & ML algorithms, approximate queries
- Witnessed significant adoption
- Many more additional systems built on the top of (and around) Spark within the BDAS:
 - Spark Streaming, GraphX, KeystoneML, MLbase, Spark SQL, BlinkDB, Tachyon, Succinct...

Spark

Motivation

Many of the previous cluster programming models are based on directed acyclic data flow from stable storage to stable storage, e.g. MapReduce, Dryad, Tez, SQL

Motivation

Many of the previous cluster programming models are based on directed acyclic data flow from stable storage to stable storage, e.g. MapReduce, Dryad, Tez, SQL

Benefits of data flow: runtime can decide where to run tasks and can automatically recover from failures

Motivation (cont'd)

- Although Acyclic data flow is a powerful abstraction, it is NOT efficient for applications that repeatedly reuse a *Working-Set* of data:
 - >> Iterative algorithms (machine learning)
 - >> Interactive data mining tools (R, Excel, Python)
- With previous frameworks, apps reload data from stable storage on each query

A Brief History of Spark

Developed in 2009 at UC Berkeley AMPLab, then open sourced in 2010, Spark has since become one of the largest OSS communities in big data, with over 200 contributors in 50+ organizations

“Organizations that are looking at big data challenges – including collection, ETL, storage, exploration and analytics – should consider Spark for its in-memory performance and the breadth of its model. It supports advanced analytics solutions on Hadoop clusters, including the iterative model required for machine learning and graph analysis.”

Gartner, Advanced Analytics and Data Science (2014)

A Brief History of Spark

circa 2010:
a unified engine for enterprise data workflows,
based on commodity hardware a decade later...

Spark: Cluster Computing with Working Sets

*Resilient Distributed Datasets: A Fault-Tolerant Abstraction for
In-Memory Cluster Computing*

Matei Zaharia, Mosharaf Chowdhury, Tathagata Das, Ankur Dave,
Justin Ma, Murphy McCauley, Michael Franklin, Scott Shenker, Ion Stoica

usenix.org/system/files/conference/nsdi12/nsdi12-final138.pdf

A Brief History of Spark

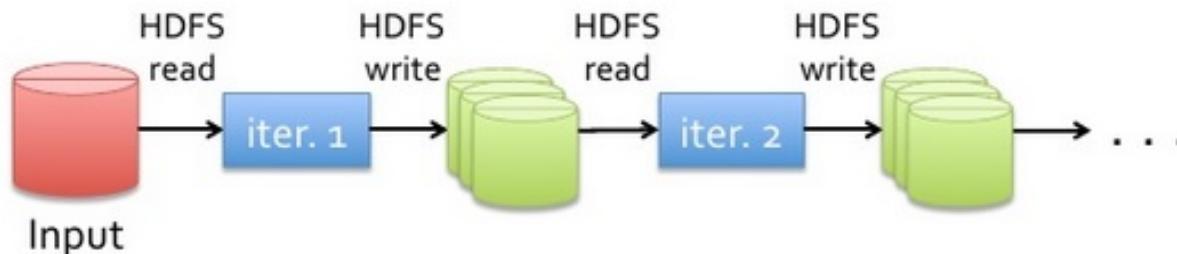

Unlike the various specialized systems, Spark's goal was to generalize MapReduce to support new apps within same engine

Two reasonably small additions are enough to express the previous models:

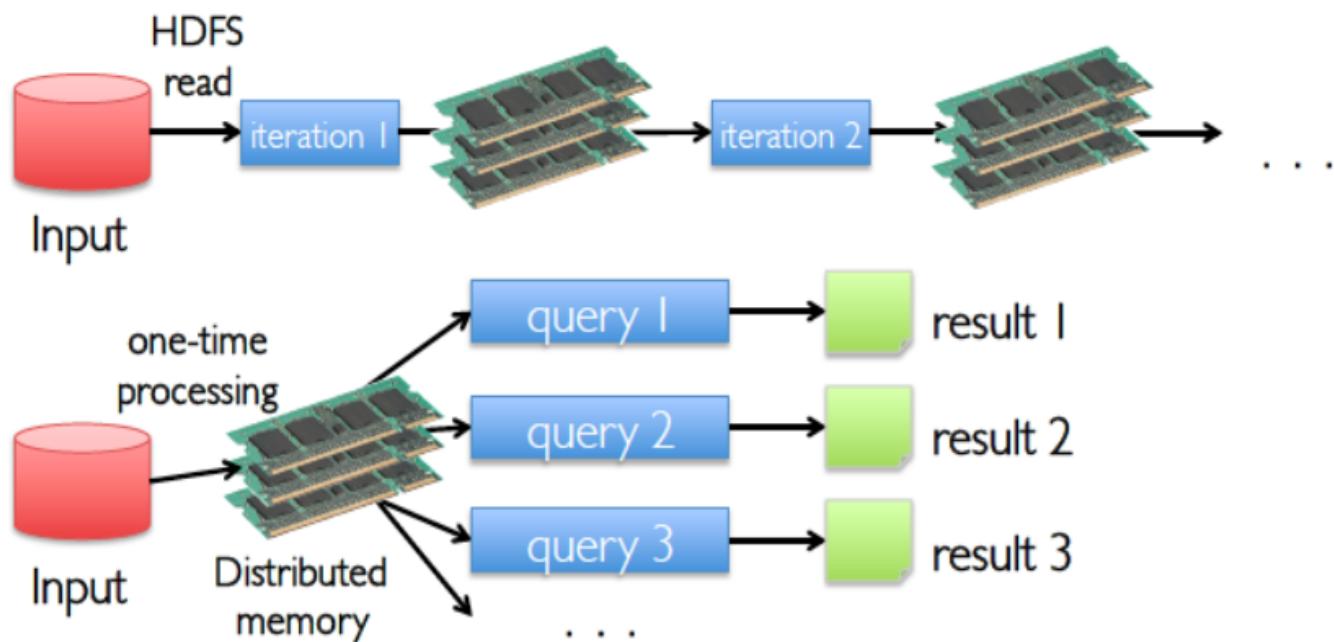

- *fast data sharing*
- *general DAGs*

Data Sharing

- MapReduce: Sharing via Disk I/O

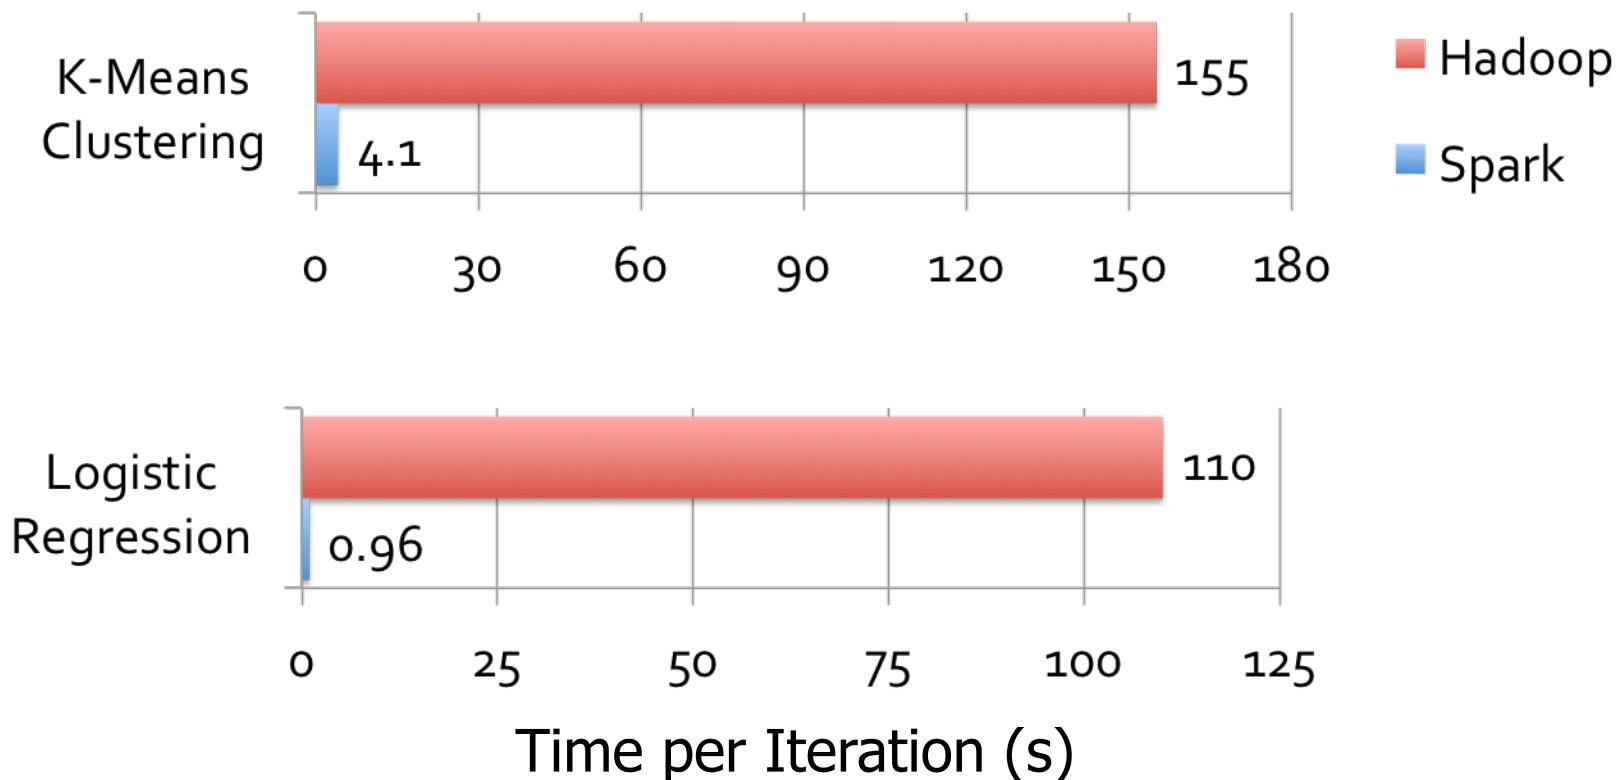

- Spark: In-memory Sharing (Fast Disk-based sharing as well)

10-100x faster than network and disk

Examples on the Performance Edge of Spark over MapReduce on some common Iterative Algorithms

Key Features of Spark

- handles batch, interactive, and real-time within a single framework
- native integration with Java, Python, Scala
- programming at a higher level of abstraction
- more general: map/reduce is just one set of supported constructs

Programming Language Support by Spark

Python

```
lines = sc.textFile(...)  
lines.filter(lambda s: "ERROR" in s).count()
```

Scala

```
val lines = sc.textFile(...)  
lines.filter(x => x.contains("ERROR")).count()
```

Java

```
JavaRDD<String> lines = sc.textFile(...);  
lines.filter(new Function<String, Boolean>() {  
    Boolean call(String s) {  
        return s.contains("error");  
    }  
}).count();
```

Standalone Programs

Python, Scala, & Java

Interactive Shells

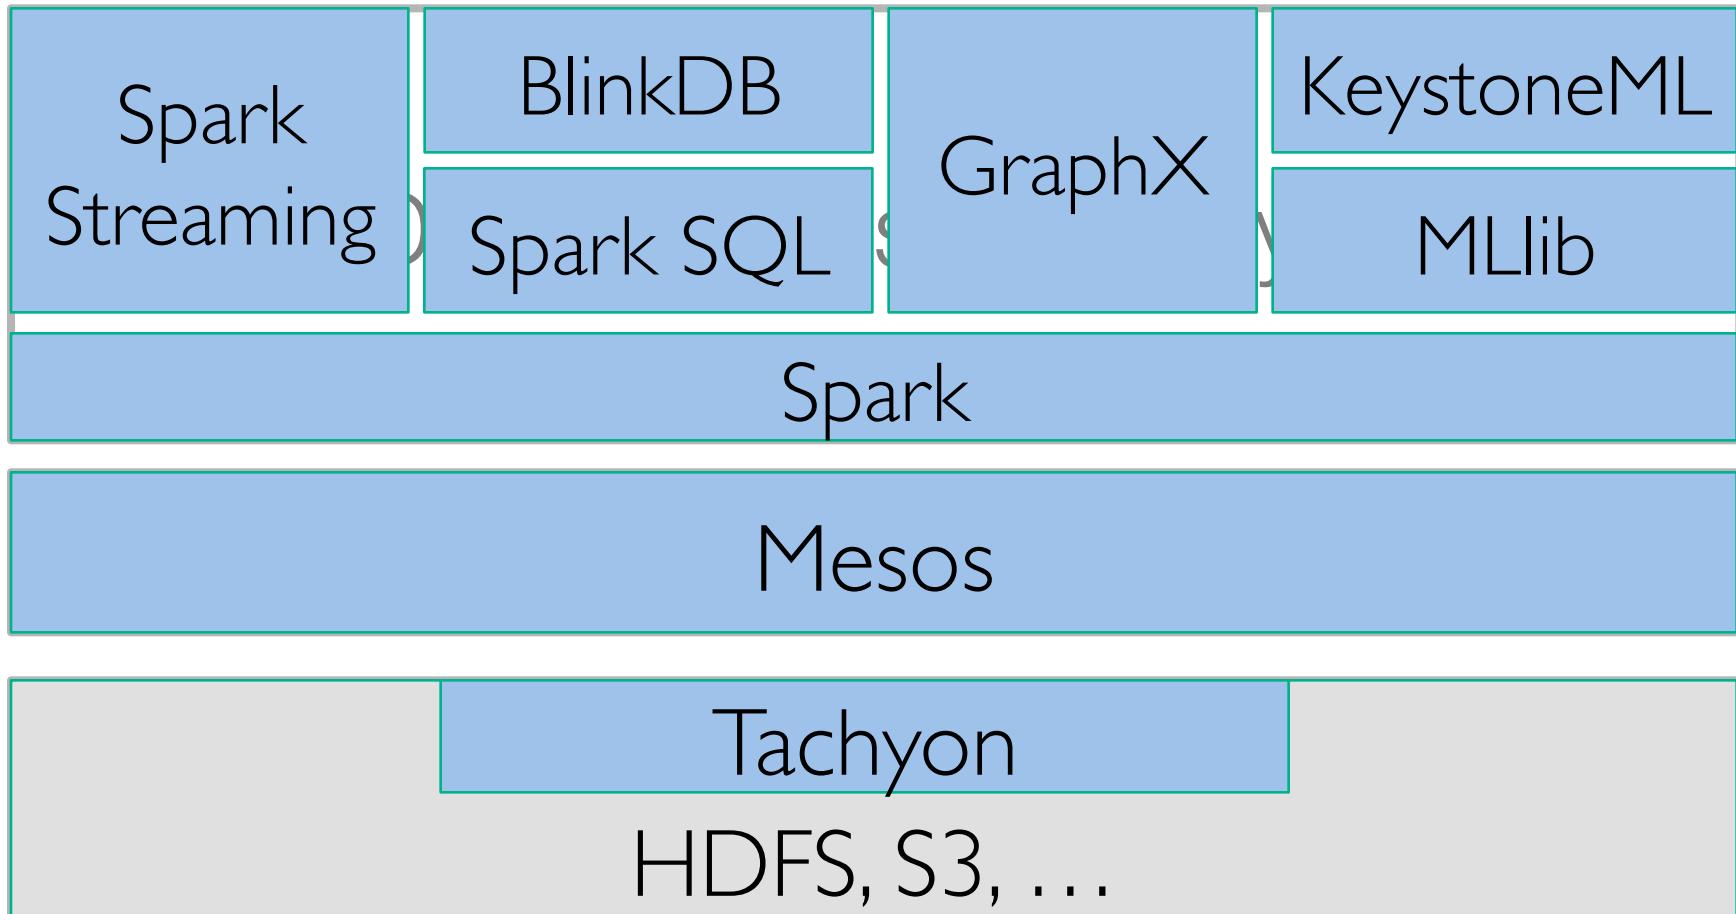

Python & Scala

Performance

Java & Scala are faster due to static typing

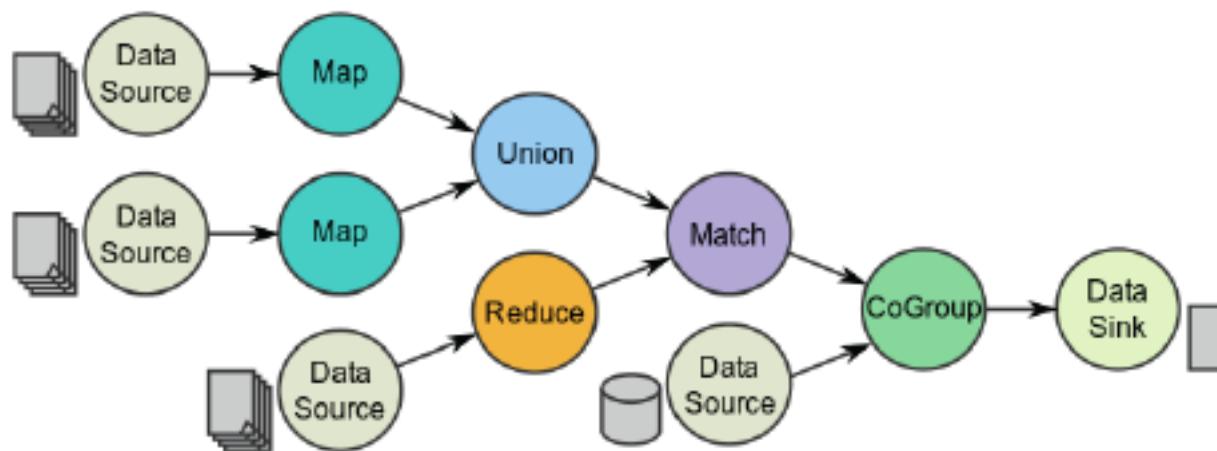

...but Python is often fine

Spark as the Core Distributed Processing Engine of BDAS

Spark's Solution: Data Flow Model + Resilient Distributed Datasets

- Augment Data Flow model with “Resilient Distributed Datasets” (RDDs)

- Combine Data Flow with RDDs to unify many cluster programming models
 - Instead of specialized APIs for one-type of apps, give users 1st-class control of **Distributed Datasets**

Outline

A Brief History: Functional Programming for Big Data

About Scala

High-level language for JVM

- >> Object-Oriented + Functional programming (FP)
- >> Designed by Martin Odersky of EPFL in 2001 ;
First public release in 2004.
- >> Odersky founded Typesafe in 2011 to provide commercial support of Scala

Statically typed

- >> Comparable in speed to Java
- >> no need to write types due to type inference

Interoperates with Java

- >> Can use any Java class, inherit from it, etc;
- >> Can also call Scala code from Java

Where to learn more

>>Odersky's Scala course on Coursera:

<https://www.coursera.org/course/progfun>

>>Odersky's OSCON 2011 keynote on why Functional Programming & Parallel-processing is a good fit: <https://www.youtube.com/watch?v=3jg1AheF4n0>

Quick Tour of Scala

Declaring variables:

```
var x: Int = 7  
var x = 7 // type inferred  
  
val y = "hi" // read-only
```

Java equivalent:

```
int x = 7;  
  
final String y = "hi";
```

Functions:

```
def square(x: Int): Int = x*x  
  
def square(x: Int): Int = {  
    x*x  
}
```

Java equivalent:

```
int square(int x) {  
    return x*x;
```

Last expression in block returned

```
def announce(text: String) {  
    println(text)  
}
```

```
void announce(String text) {  
    System.out.println(text);  
}
```

Quick Tour of Scala (cont'd)

Generic types:

```
var arr = new Array[Int](8)
```

```
var lst = List(1, 2, 3)
```

```
// type of lst is List[Int]
```

Java equivalent:

```
int[] arr = new int[8];
```

```
List<Integer> lst =  
    new ArrayList<Integer>();  
lst.add(...)
```

Indexing:

```
arr(5) = 7
```

```
println(lst(5))
```

Java equivalent:

```
arr[5] = 7;
```

```
System.out.println(lst.get(5));
```

Quick Tour of Scala (cont'd)

Processing collections with functional programming:

```
val list = List(1, 2, 3)      Function expression (closure)  
  
list.foreach(x => println(x)) // prints 1, 2, 3  
list.foreach(println)         // same  
  
list.map(x => x + 2)        // => List(3, 4, 5)  
list.map(_ + 2)              // same, with placeholder notation  
  
list.filter(x => x % 2 == 1) // => List(1, 3)  
list.filter(_ % 2 == 1)       // => List(1, 3)  
  
list.reduce((x, y) => x + y) // => 6  
list.reduce(_ + _)           // => 6
```

All of these leave the list unchanged (List is Immutable)

Scala Closure Syntax (cont'd)

```
(x: Int) => x + 2    // full version  
  
x => x + 2    // type inferred  
  
_ + 2          // when each argument is used exactly once  
  
x => {          // when body is a block of code  
  val numberToAdd = 2  
  x + numberToAdd  
}  
  
// If closure is too long, can always pass a function  
def addTwo(x: Int): Int = x + 2  
  
list.map(addTwo)
```

Scala allows defining a “local function” inside another function

Scala Cheat Sheet

Variables:

```
var x: Int = 7
var x = 7      // type inferred
val y = "hi"   // read-only
```

Functions:

```
def square(x: Int): Int = x*x

def square(x: Int): Int = {
  x*x    // last line returned
}
```

Collections and closures:

```
val nums = Array(1, 2, 3)
nums.map(x: Int) => x + 2) // => Array(3, 4, 5)
nums.map(x => x + 2)    // => same
nums.map(_ + 2)          // => same
nums.reduce((x, y) => x + y) // => 6
nums.reduce(_ + _)        // => 6
```

Java interop:

```
import java.net.URL
new URL("http://
cnn.com").openStream()
```

More details:
scala-lang.org

Other Scala Collection Methods

More details:
scala-lang.org

Scala collections provide many other functional methods; for example, Google for “Scala Seq”

Method on Seq[T]	Explanation
<code>map(f: T => U): Seq[U]</code>	Pass each element through f
<code>flatMap(f: T => Seq[U]): Seq[U]</code>	One-to-many map
<code>filter(f: T => Boolean): Seq[T]</code>	Keep elements passing f
<code>exists(f: T => Boolean): Boolean</code>	True if one element passes
<code>forall(f: T => Boolean): Boolean</code>	True if all elements pass
<code>reduce(f: (T, T) => T): T</code>	Merge elements using f
<code>groupBy(f: T => K): Map[K, List[T]]</code>	Group elements by f(element)
<code>sortBy(f: T => K): Seq[T]</code>	Sort elements by f(element)
...	

Outline

- Introduction to Functional programming & Scala
- Spark's Resilient Distributed Datasets (RDDs)
- Implementation
- Conclusion

Key Ideas behind Spark

- Spark makes **Working Datasets** a first-class concept to efficiently support **In-memory Data-Sharing** across (different iterations/ stages of) apps
- Provide **Distributed Memory Abstractions** (**called Resilient Distributed Datasets - RDDs**) for clusters to support apps with Working Sets
 - Work with distributed collections as you would with local ones
- Retain the attractive properties of MapReduce:
 - Fault tolerance (for crashes & stragglers)
 - Data locality
 - Scalability
- Enhance programmability:
 - Integrate into Scala programming language
 - Allow interactive use from Scala interpreter

What are Resilient Distributed Datasets (RDDs) ?

- RDDs are **Immutable** (i.e. become read-only once they are created) collections **partitioned across cluster** that **can be rebuilt** if a partition is lost
 - Created by transforming data in **stable storage** using data flow operators (map, filter, group-by, ...)
 - The elements of an RDD need not exist in physical storage;
 - Instead, a handle to an RDD contains enough information (**aka lineage info**) to compute the RDD starting from data in reliable storage.
- =>RDDs can always be reconstructed if nodes fail.

What are RDDs (cont'd) ?

- RDDs that can be *cached* (aka *persist*) in RAM across parallel operations and to be shared by different Apps
- User can control the *Partitioning* of an RDD, e.g .one comprised of <key,value> pairs based on hash or range of the key.
 - Once partitioned, Spark will remember the way an RDD is partitioned and use the info to reduce unnecessary data shuffling when operating on RDDs
 - e.g. Functions that benefit from partitioning include: cogroup(), groupWith(), join() , groupByKey(), reduceByKey(), combineByKey(), lookup()
 - Spark knows internally which operations may affect partitioning, and will automatically set the partitioner of an RDD

RDD Types: Parallelized Collections

- By calling SparkContext's parallelize method on an existing Scala collection (a Seq obj)

```
scala> val data = Array(1,2,3,4,5)
data: Array[Int] = Array(1, 2, 3, 4, 5)

scala> val distData = sc.parallelize(data)
distData: spark.RDD[Int] = spark.ParallelCollection@3b9c5ce6
```

- Once created, the distributed dataset can be operated on in parallel

RDD Types: Hadoop Datasets

- Spark supports text files, SequenceFiles, and any other Hadoop inputFormat

Local path or hdfs://, s3n://, kfs://

```
val distFiles = sc.textFile(URI)
```

- Other Hadoop inputFormat

```
val distFile = sc.hadoopRDD(URI)
```

Programming Model of Spark

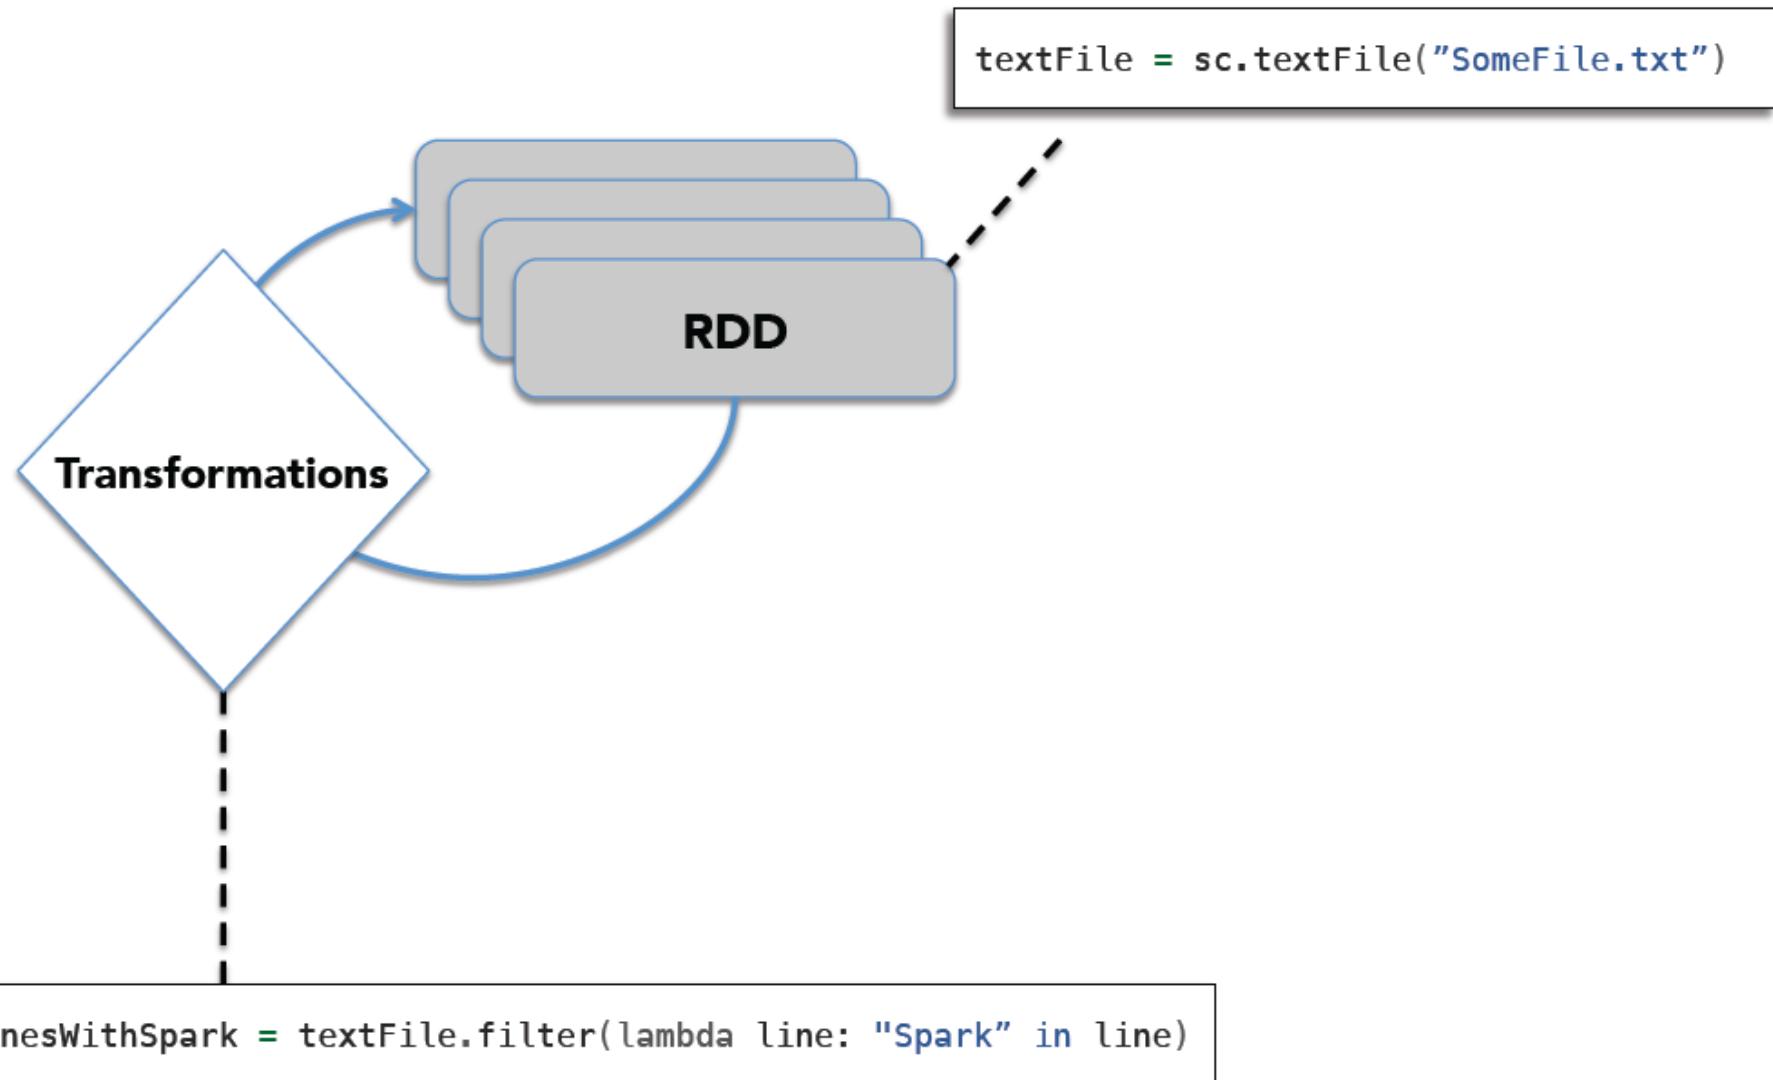

- Use Resilient Distributed Datasets (RDDs) as basic building blocks
- Perform Parallel Operations on RDDs
 - **Transformations**: Operations to create new RDD(s) from existing ones, e.g. map, filter, groupBy, join ;
 - **Actions**: Return a result (value) to a driver program after running the computation on the RDD or write it to storage, e.g. reduce, collect, count, save ...
 - Transformations **are Lazy (They don't compute right away)**:
 - Spark just remembers the transformations applied to datasets(lineage). **Only compute when an action requires.**
- **Restricted Shared Variables**
 - Accumulators, Broadcast variables

Working with RDDs

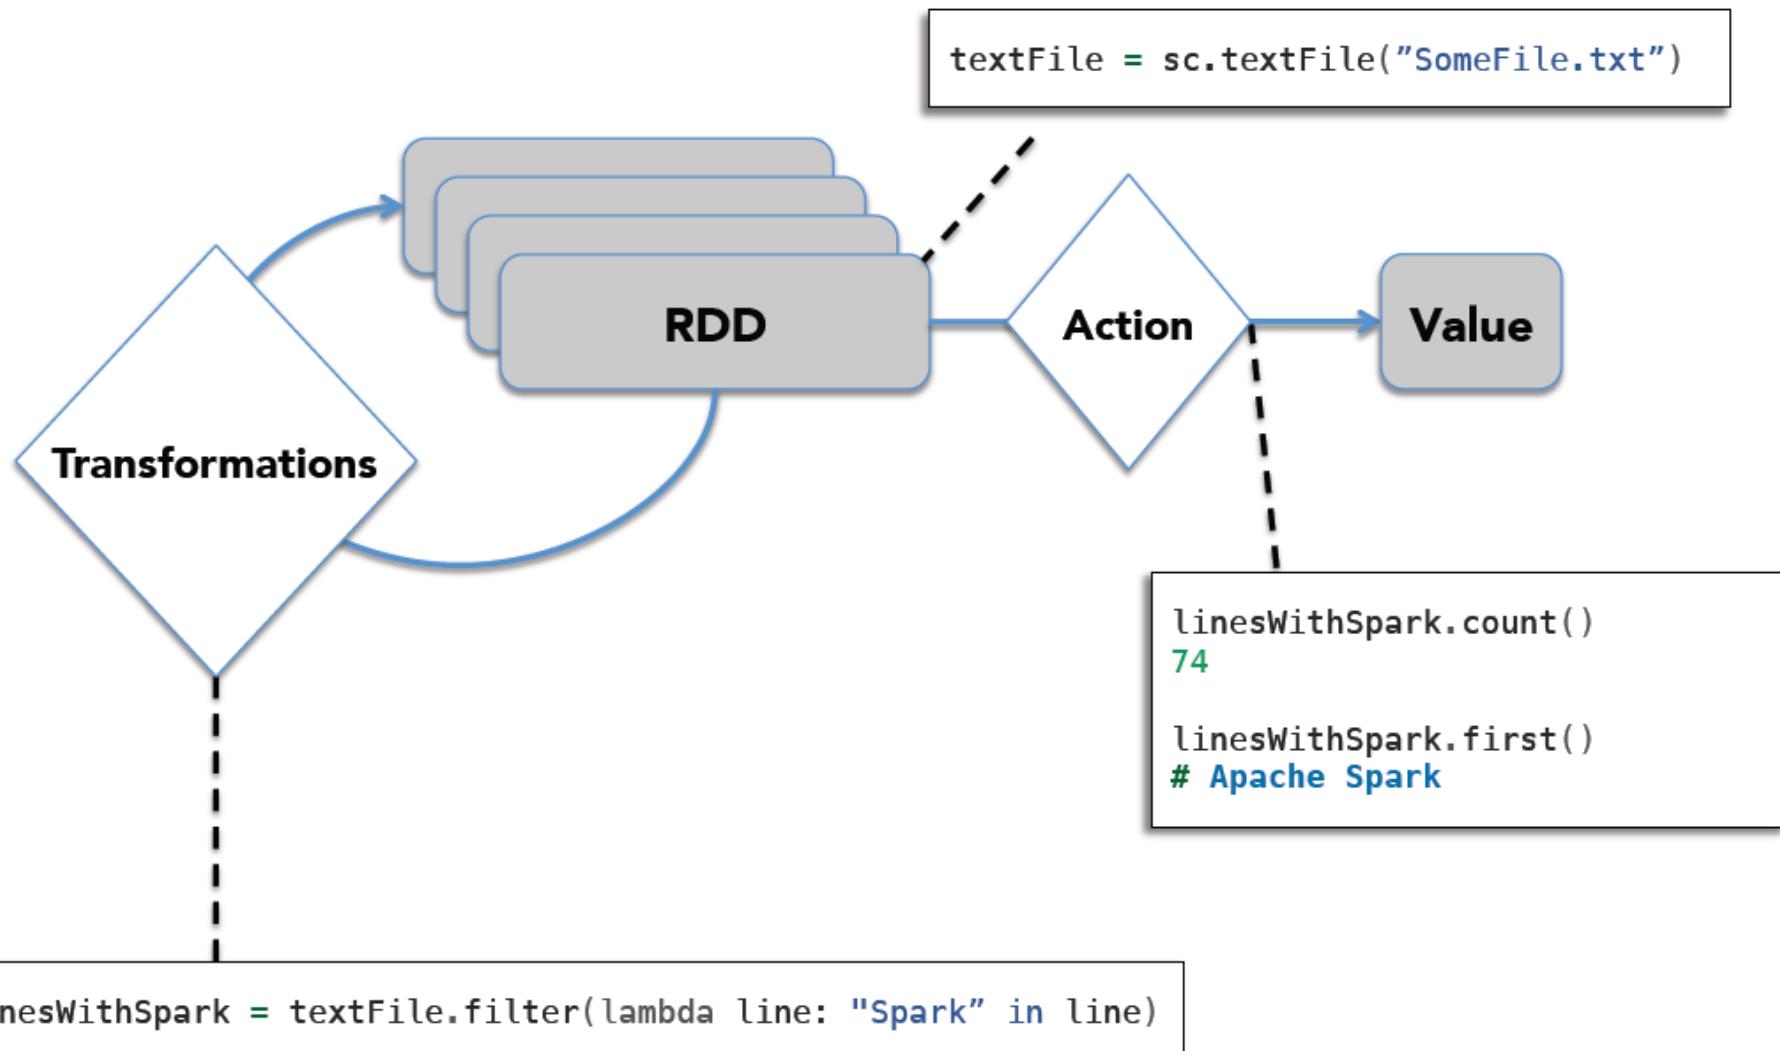

```
textFile = sc.textFile("SomeFile.txt")
```

RDD

Working with RDDs

Working with RDDs

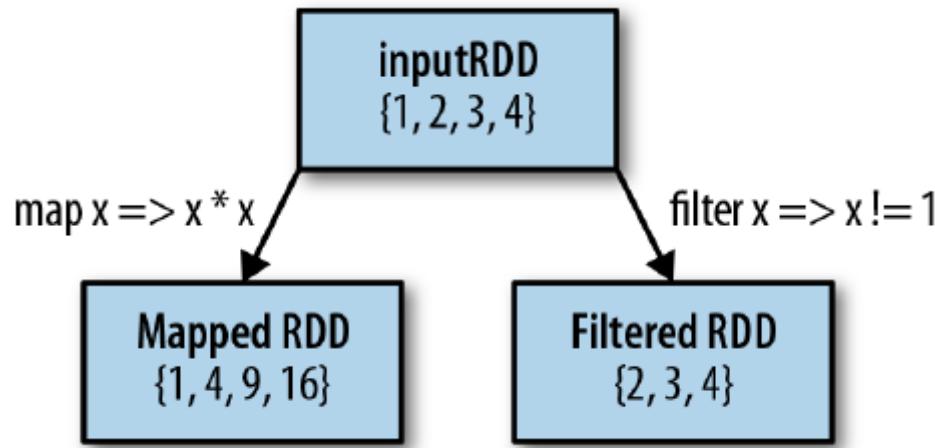

Transformations

<i>transformation</i>	<i>description</i>
map (<i>func</i>)	return a new distributed dataset formed by passing each element of the source through a function <i>func</i>
filter (<i>func</i>)	return a new dataset formed by selecting those elements of the source on which <i>func</i> returns true
flatMap (<i>func</i>)	similar to map, but each input item can be mapped to 0 or more output items (so <i>func</i> should return a Seq rather than a single item)
sample (<i>withReplacement</i> , <i>fraction</i> , <i>seed</i>)	sample a fraction <i>fraction</i> of the data, with or without replacement, using a given random number generator seed
union (<i>otherDataset</i>)	return a new dataset that contains the union of the elements in the source dataset and the argument
distinct ([<i>numTasks</i>]))	return a new dataset that contains the distinct elements of the source dataset

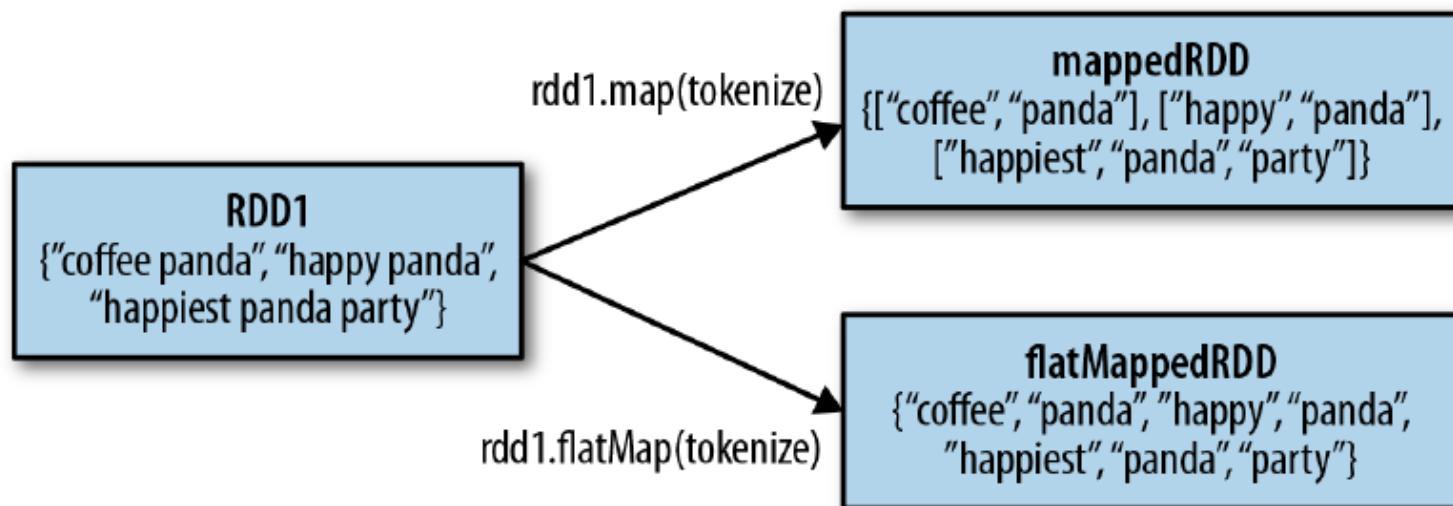

Transformations (cont'd)

<i>transformation</i>	<i>description</i>
groupByKey([numTasks])	when called on a dataset of (K, V) pairs, returns a dataset of (K, Seq[V]) pairs
reduceByKey(func, [numTasks])	when called on a dataset of (K, V) pairs, returns a dataset of (K, V) pairs where the values for each key are aggregated using the given reduce function
sortByKey([ascending], [numTasks])	when called on a dataset of (K, V) pairs where K implements Ordered, returns a dataset of (K, V) pairs sorted by keys in ascending or descending order, as specified in the boolean ascending argument
join(otherDataset, [numTasks])	when called on datasets of type (K, V) and (K, W), returns a dataset of (K, (V, W)) pairs with all pairs of elements for each key
cogroup(otherDataset, [numTasks])	when called on datasets of type (K, V) and (K, W), returns a dataset of (K, Seq[V], Seq[W]) tuples – also called groupWith
cartesian(otherDataset)	when called on datasets of types T and U, returns a dataset of (T, U) pairs (all pairs of elements)

Transformations Examples

`tokenize("coffee panda") = List("coffee", "panda")`

Examples on Set Operations

RDD1

{coffee, coffee, panda,
monkey, tea}

RDD2

{coffee, money, kitty}

RDD1.distinct()
{coffee, panda,
monkey, tea}

RDD1.union(RDD2)
{coffee, coffee, coffee,
panda, monkey,
monkey, tea, kitty}

RDD1.intersection(RDD2)
{coffee, monkey}

RDD1.subtract(RDD2)
{panda, tea}

Examples on Set Operations

RDD1

{coffee, coffee, panda,
monkey, tea}

RDD2

{coffee, money, kitty}

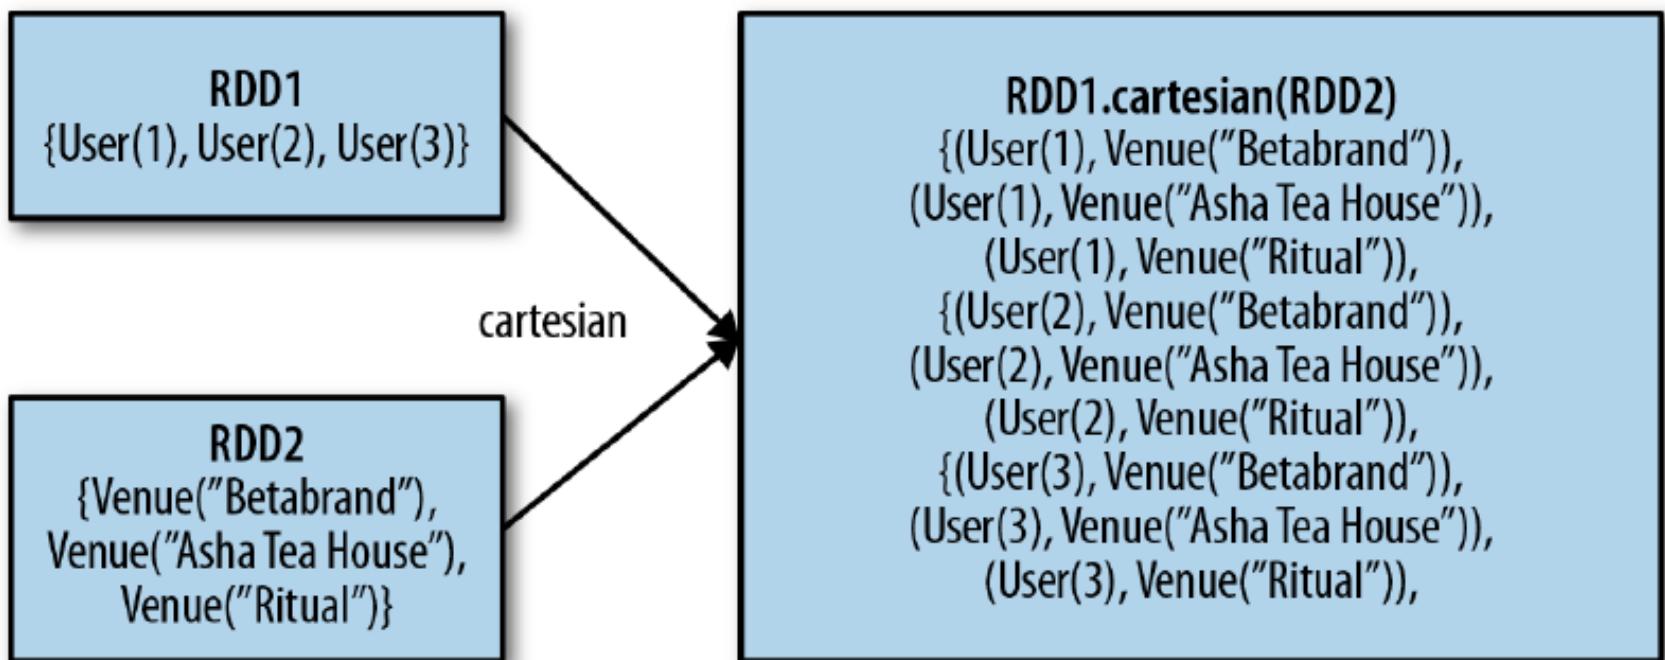

RDD1.distinct()
{coffee, panda,
monkey, tea}

RDD1.union(RDD2)
{coffee, coffee, coffee,
panda, monkey,
monkey, tea, kitty}

RDD1.intersection(RDD2)
{coffee, monkey}

RDD1.subtract(RDD2)
{panda, tea}

Examples on Cartesian product b/w two RDDs

More Examples Basic RDD Transformations

Table 3-2. Basic RDD transformations on an RDD containing {1, 2, 3, 3}

Function name	Purpose	Example	Result
map()	Apply a function to each element in the RDD and return an RDD of the result.	rdd.map(x => x + 1)	{2, 3, 4, 4}
flatMap()	Apply a function to each element in the RDD and return an RDD of the contents of the iterators returned. Often used to extract words.	rdd.flatMap(x => x.to(3))	{1, 2, 3, 2, 3, 3}
filter()	Return an RDD consisting of only elements that pass the condition passed to filter().	rdd.filter(x => x != 1)	{2, 3, 3}
distinct()	Remove duplicates.	rdd.distinct()	{1, 2, 3}
sample(withReplacement, fraction, [seed])	Sample an RDD, with or without replacement.	rdd.sample(false, 0.5)	Nondeterministic

More Examples Basic RDD Transformations (cont'd)

Table 3-3. Two-RDD transformations on RDDs containing {1, 2, 3} and {3, 4, 5}

Function name	Purpose	Example	Result
union()	Produce an RDD containing elements from both RDDs.	rdd.union(other)	{1, 2, 3, 3, 4, 5}
intersection()	RDD containing only elements found in both RDDs.	rdd.intersection(other)	{3}
subtract()	Remove the contents of one RDD (e.g., remove training data).	rdd.subtract(other)	{1, 2}
cartesian()	Cartesian product with the other RDD.	rdd.cartesian(other)	{(1, 3), (1, 4), ... (3,5)}

More Transformations Example

Scala:

```
val distFile = sqlContext.table("readme").map(_(0).asInstanceOf[String])
distFile.map(l => l.split(" ")).collect()
distFile.flatMap(l => l.split(" ")).collect()
```

distFile is a collection of lines

Python:

```
distFile = sqlContext.table("readme").map(lambda x: x[0])
distFile.map(lambda x: x.split(' ')).collect()
distFile.flatMap(lambda x: x.split(' ')).collect()
```

More Transformations Example

Scala:

```
val distFile = sqlContext.table("readme").map(_(0).asInstanceOf[String])  
distFile.map(l => l.split(" ")).collect()  
distFile.flatMap(l => l.split(" ")).collect()
```

closures

Python:

```
distFile = sqlContext.table("readme").map(lambda x: x[0])  
distFile.map(lambda x: x.split(' ')).collect()  
distFile.flatMap(lambda x: x.split(' ')).collect()
```

Actions

action	description
reduce(func)	aggregate the elements of the dataset using a function <i>func</i> (which takes two arguments and returns one), and should also be commutative and associative so that it can be computed correctly in parallel
collect()	return all the elements of the dataset as an array at the driver program – usually useful after a filter or other operation that returns a sufficiently small subset of the data
count()	return the number of elements in the dataset
first()	return the first element of the dataset – similar to <i>take(1)</i>
take(n)	return an array with the first <i>n</i> elements of the dataset – currently not executed in parallel, instead the driver program computes all the elements
takeSample(withReplacement, fraction, seed)	return an array with a random sample of <i>num</i> elements of the dataset, with or without replacement, using the given random number generator seed

Actions (cont'd)

<i>action</i>	<i>description</i>
saveAsTextFile(path)	write the elements of the dataset as a text file (or set of text files) in a given directory in the local filesystem, HDFS or any other Hadoop-supported file system. Spark will call <code>toString</code> on each element to convert it to a line of text in the file
saveAsSequenceFile(path)	write the elements of the dataset as a Hadoop SequenceFile in a given path in the local filesystem, HDFS or any other Hadoop-supported file system. Only available on RDDs of key-value pairs that either implement Hadoop's <code>writable</code> interface or are implicitly convertible to <code>writable</code> (Spark includes conversions for basic types like <code>Int</code> , <code>Double</code> , <code>String</code> , etc).
countByKey()	only available on RDDs of type <code>(K, V)</code> . Returns a 'Map' of <code>(K, Int)</code> pairs with the count of each key
foreach(func)	run a function <code>func</code> on each element of the dataset – usually done for side effects such as updating an accumulator variable or interacting with external storage systems

Examples of Actions on RDDs

Table 3-4. Basic actions on an RDD containing {1, 2, 3, 3}

Function name	Purpose	Example	Result
collect()	Return all elements from the RDD.	rdd.collect()	{1, 2, 3, 3}
count()	Number of elements in the RDD.	rdd.count()	4
countByValue()	Number of times each element occurs in the RDD.	rdd.countByValue()	{(1, 1), (2, 1), (3, 2)}
take(num)	Return num elements from the RDD.	rdd.take(2)	{1, 2}
top(num)	Return the top num elements the RDD.	rdd.top(2)	{3, 3}
takeOrdered(num)(ordering)	Return num elements based on provided ordering.	rdd.takeOrdered(2)(myOrdering)	{3, 3}

More Examples of Actions on RDDs

Table 3-4. Basic actions on an RDD containing {1, 2, 3, 3}

Function name	Purpose	Example	Result
<code>takeSample(withReplacement, num, [seed])</code>	Return num elements at random.	<code>rdd.takeSample(false, 1)</code>	Nondeterministic
<code>reduce(func)</code>	Combine the elements of the RDD together in parallel (e.g., sum).	<code>rdd.reduce((x, y) => x + y)</code>	9
<code>fold(zero)(func)</code>	Same as <code>reduce()</code> but with the provided zero value.	<code>rdd.fold(0)((x, y) => x + y)</code>	9
<code>aggregate(zeroValue)(seqOp, combOp)</code>	Similar to <code>reduce()</code> but used to return a different type.	<code>rdd.aggregate((0, 0))((x, y) => (x._1 + y, x._2 + 1), (x, y) => (x._1 + y._1, x._2 + y._2))</code>	(9, 4)
<code>foreach(func)</code>	Apply the provided function to each element of the RDD.	<code>rdd.foreach(func)</code>	Nothing

More Action Examples

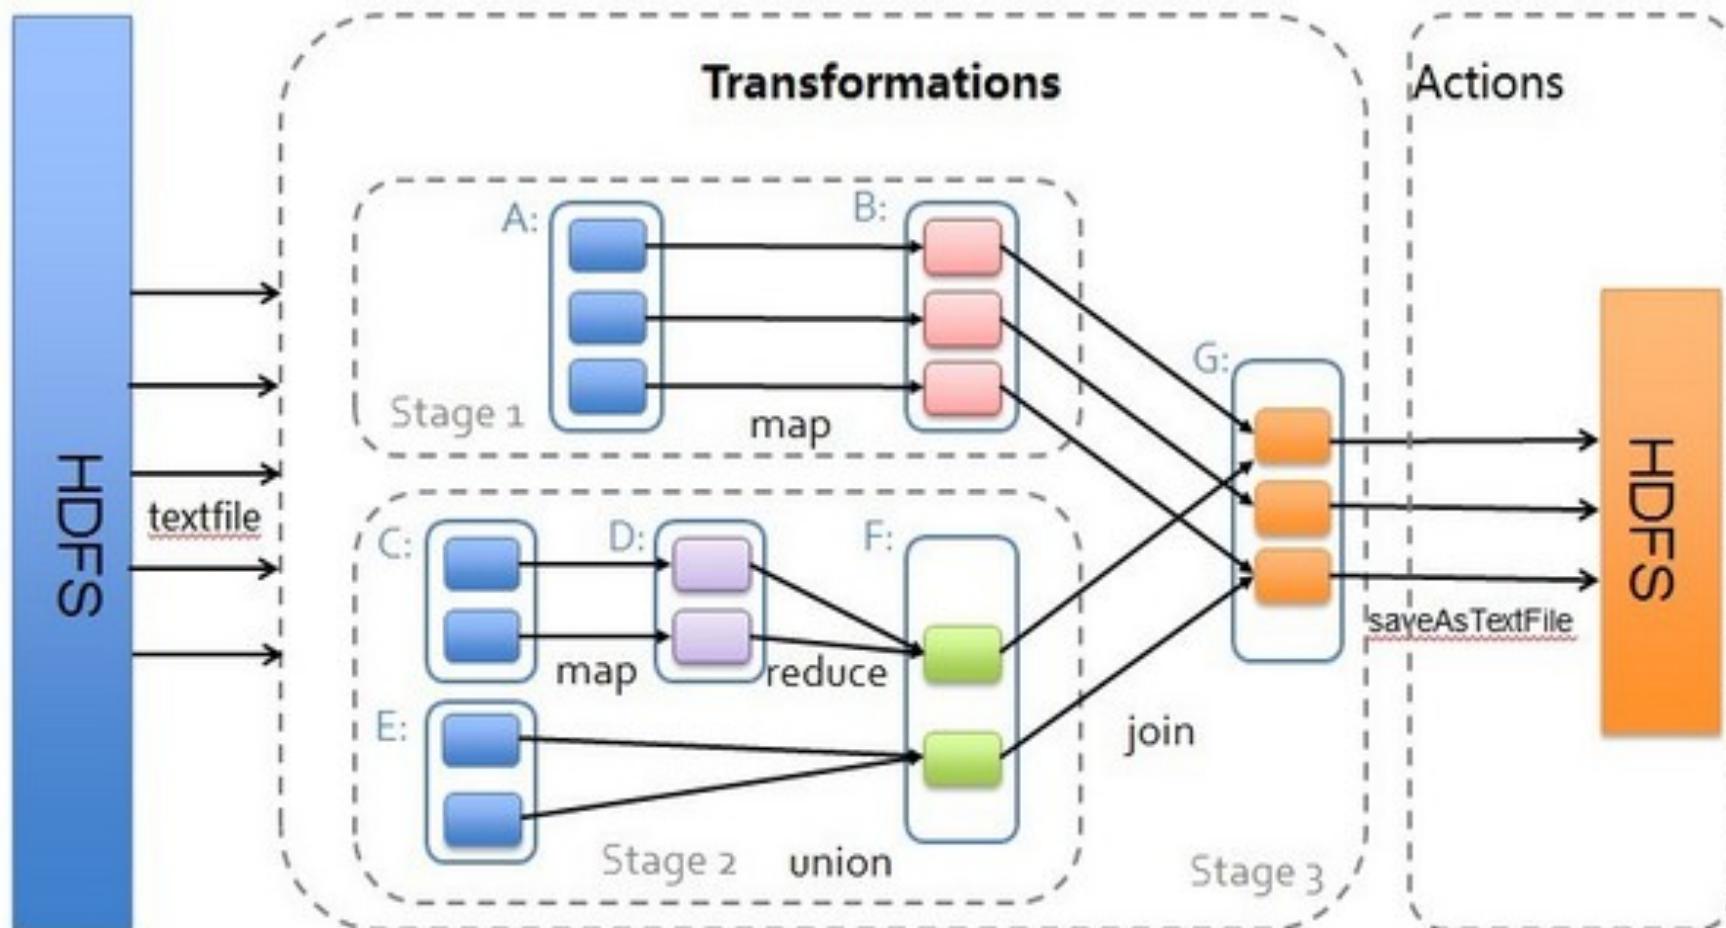

Scala:

```
val distFile = sqlContext.table("readme").map(_(0).asInstanceOf[String])
val words = f.flatMap(l => l.split(" ")).map(word => (word, 1))
words.reduceByKey(_ + _).collect.foreach(println)
```

Python:

```
from operator import add
f = sqlContext.table("readme").map(lambda x: x[0])
words = f.flatMap(lambda x: x.split(' ')).map(lambda x: (x, 1))
words.reduceByKey(add).collect()
```

Transformations & Actions

Parallel Operations

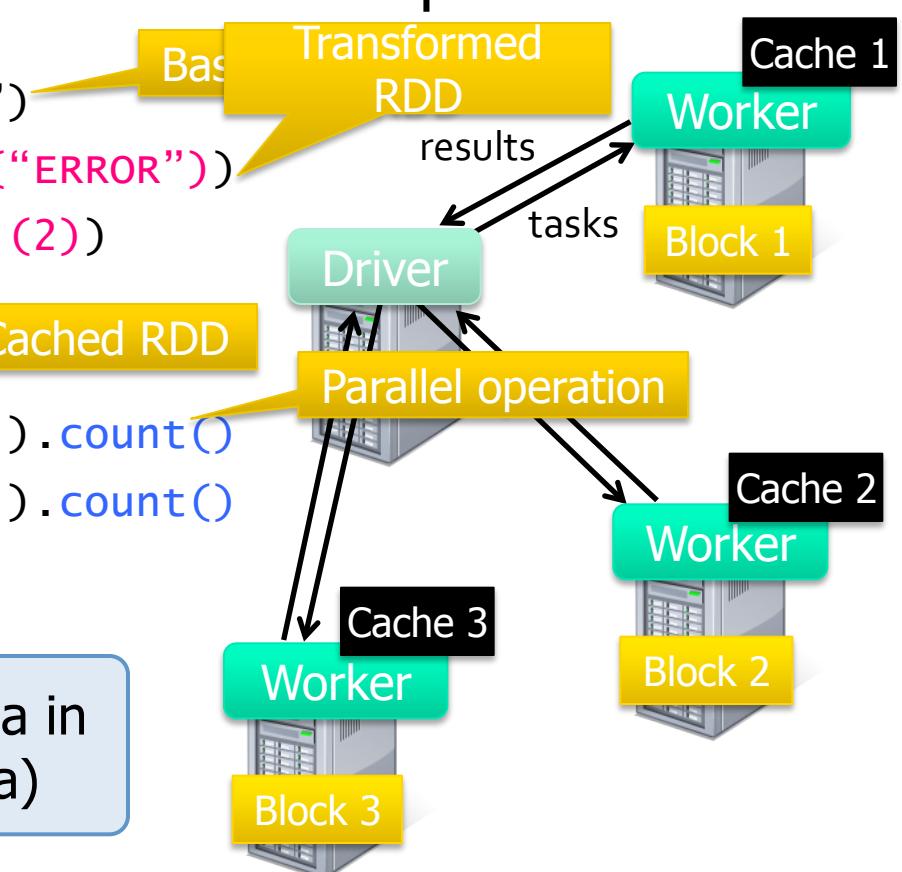

- **reduce:** Combines dataset elements using an associative function to produce a result at the driver program.
- **collect:** Sends all elements of the dataset to the driver program.

Example: Log Mining w/ Spark in Scala

- Load error messages from a log into memory, then interactively search for various patterns

```
lines = spark.textFile("hdfs://...")  
errors = lines.filter(_.startsWith("ERROR"))  
messages = errors.map(_.split("\t")(2))  
cachedMsgs = messages.cache()
```

```
cachedMsgs.filter(_.contains("foo")).count()  
cachedMsgs.filter(_.contains("bar")).count()  
...
```

Result: full-text search of Wikipedia in <1 sec (vs 20 sec for on-disk data)

Spark in Scala and Java

```
// Scala:  
  
val lines = sc.textFile(...)  
lines.filter(x => x.contains("ERROR")).count()  
  
//the line above is the long form of:  
  
// lines.filter(_.contains("ERROR")).count()
```

```
// Java:  
  
JavaRDD<String> lines = sc.textFile(...);  
lines.filter(new Function<String, Boolean>() {  
    Boolean call(String s) {  
        return s.contains("error");  
    }  
}).count();
```

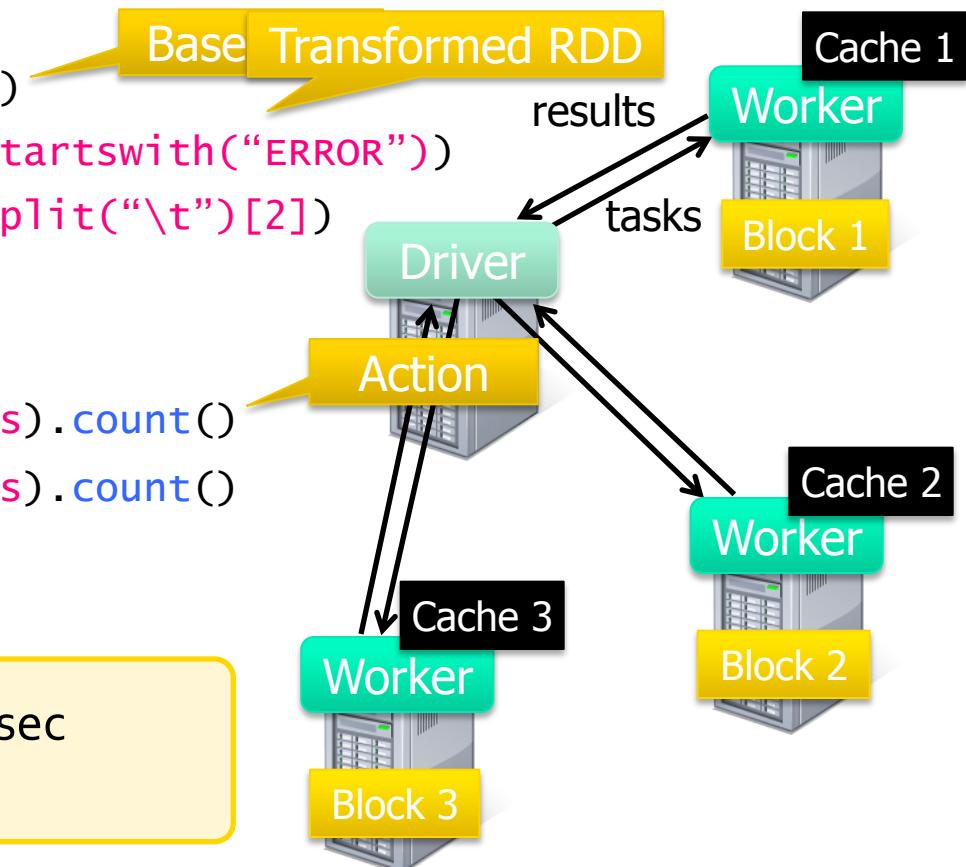

Same Example in Python

Load error messages from a log into memory,
then interactively search for various patterns

```
lines = spark.textFile("hdfs://...")  
errors = lines.filter(lambda s: s.startswith("ERROR"))  
messages = errors.map(lambda s: s.split("\t")[2])  
messages.cache()
```

```
messages.filter(lambda s: "foo" in s).count()  
messages.filter(lambda s: "bar" in s).count()  
...
```

Result: scaled to 1 TB data in 5 sec
(vs 180 sec for on-disk data)

Working with Key-Value Pairs

- Spark's "distributed reduce" transformations operate on RDDs of key-value pairs
- Python:

```
pair = (a, b)
       pair[0] # => a
       pair[1] # => b
```
- Scala:

```
val pair = (a, b)
           pair._1 // => a
           pair._2 // => b
```
- Java:

```
Tuple2 pair = new Tuple2(a, b);
        pair._1 // => a
        pair._2 // => b
```

Examples of Transformations on Pair RDDs

Table 4-1. Transformations on one pair RDD (example: $\{(1, 2), (3, 4), (3, 6)\}$)

Function name	Purpose	Example	Result
<code>reduceByKey(func)</code>	Combine values with the same key.	<code>rdd.reduceByKey((x, y) => x + y)</code>	$\{(1, 2), (3, 4), (3, 6)\}$
<code>groupByKey()</code>	Group values with the same key.	<code>rdd.groupByKey()</code>	$\{(1, [2]), (3, [4, 6])\}$
<code>mapValues(func)</code>	Apply a function to each value of a pair RDD without changing the key.	<code>rdd.mapValues(x => x+1)</code>	$\{(1, 3), (3, 5), (3, 7)\}$
<code>flatMapValues(func)</code>	Apply a function that returns an iterator to each value of a pair RDD, and for each element returned, produce a key/value entry with the old key. Often used for tokenization.	<code>rdd.flatMapValues(x => (x to 5))</code>	$\{(1, 2), (1, 3), (1, 4), (1, 5), (3, 4), (3, 5), (5, 4), (5, 5)\}$

More Examples of Transformations on Pair RDDs

Table 4-1. Transformations on one pair RDD (example: $\{(1, 2), (3, 4), (3, 6)\}$)

Function name	Purpose	Example	Result
keys()	Return an RDD of just the keys.	<code>rdd.keys()</code>	{1, 3, 3}
values()	Return an RDD of just the values.	<code>rdd.values()</code>	{2, 4, 6}
sortByKey()	Return an RDD sorted by the key.	<code>rdd.sortByKey()</code>	{(1, 2), (3, 4), (3, 6)}
combineBy Key(createCombiner, mergeValue, mergeCombiners, partitioner)	Combine values with the same key using a different result type.		

More Examples of Transformations on Pair RDDs

Table 4-2. Transformations on two pair RDDs ($rdd = \{(1, 2), (3, 4), (3, 6)\}$ other = $\{(3, 9)\}$)

Function name	Purpose	Example	Result
subtractByKey	Remove elements with a key present in the other RDD.	<code>rdd.subtractByKey(other)</code>	$\{(1, 2)\}$
join	Perform an inner join between two RDDs.	<code>rdd.join(other)</code>	$\{(3, (4, 9)), (3, (6, 9))\}$
rightOuterJoin	Perform a join between two RDDs where the key must be present in the first RDD.	<code>rdd.rightOuterJoin(other)</code>	$\{(3, (\text{Some}(4), 9)), (3, (\text{Some}(6), 9))\}$
leftOuterJoin	Perform a join between two RDDs where the key must be present in the other RDD.	<code>rdd.leftOuterJoin(other)</code>	$\{(1, (\text{None}, 2)), (3, (\text{Some}(4), 9)), (3, (\text{Some}(6), 9))\}$
cogroup	Group data from both RDDs sharing the same key.	<code>rdd.cogroup(other)</code>	$\{(1, ([2], [])), (3, ([4, 6], [9]))\}$

Example of using combineByKey to compute Per-key averaging for Pair RDDs in Python or Scala

Example 4-12. Per-key average using combineByKey() in Python

```
sumCount = nums.combineByKey((lambda x: (x,1)),
                             (lambda x, y: (x[0] + y, x[1] + 1)),
                             (lambda x, y: (x[0] + y[0], x[1] + y[1])))
sumCount.map(lambda key, xy: (key, xy[0]/xy[1])).collectAsMap()
```

Example 4-13. Per-key average using combineByKey() in Scala

```
val result = input.combineByKey(
  (v) => (v, 1),
  (acc: (Int, Int), v) => (acc._1 + v, acc._2 + 1),
  (acc1: (Int, Int), acc2: (Int, Int)) => (acc1._1 + acc2._1, acc1._2 + acc2._2)
).map{ case (key, value) => (key, value._1 / value._2.toFloat) }
result.collectAsMap().map(_.println)
```

Examples of combineByKey for Pair RDDs in Java

Example 4-14. Per-key average using combineByKey() in Java

```
public static class AvgCount implements Serializable {
    public AvgCount(int total, int num) {    total_ = total;    num_ = num; }
    public int total_;
    public int num_;
    public float avg() {    return total_ / (float) num_; }
}

Function<Integer, AvgCount> createAcc = new Function<Integer, AvgCount>() {
    public AvgCount call(Integer x) {
        return new AvgCount(x, 1);
    }
};
Function2<AvgCount, Integer, AvgCount> addAndCount =
    new Function2<AvgCount, Integer, AvgCount>() {
    public AvgCount call(AvgCount a, Integer x) {
        a.total_ += x;
        a.num_ += 1;
        return a;
    }
};
Function2<AvgCount, AvgCount, AvgCount> combine =
    new Function2<AvgCount, AvgCount, AvgCount>() {
    public AvgCount call(AvgCount a, AvgCount b) {
        a.total_ += b.total_;
        a.num_ += b.num_;
        return a;
    }
};
AvgCount initial = new AvgCount(0,0);
JavaPairRDD<String, AvgCount> avgCounts =
    nums.combineByKey(createAcc, addAndCount, combine);
Map<String, AvgCount> countMap = avgCounts.collectAsMap();
for (Entry<String, AvgCount> entry : countMap.entrySet()) {
    System.out.println(entry.getKey() + ":" + entry.getValue().avg());
}
```

Examples of Filtering on Values of a Pair-RDD

Example 4-4. Simple filter on second element in Python

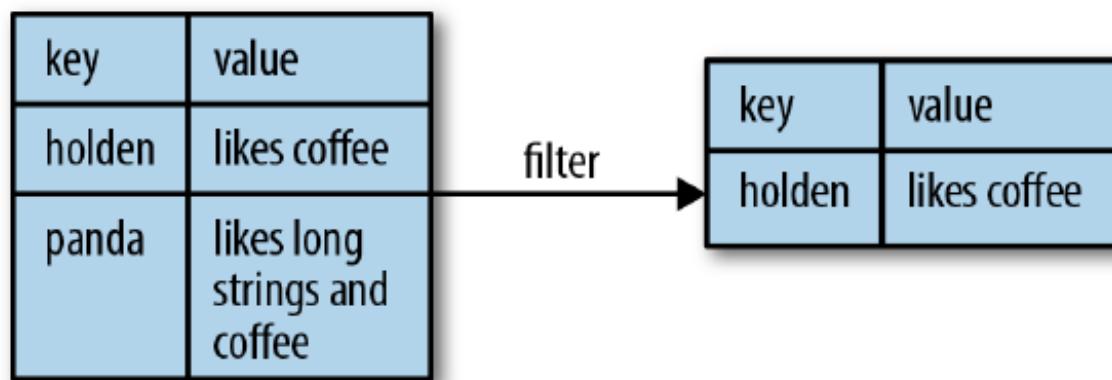

```
result = pairs.filter(lambda keyValue: len(keyValue[1]) < 20)
```

Example 4-5. Simple filter on second element in Scala

```
pairs.filter{case (key, value) => value.length < 20}
```

Example 4-6. Simple filter on second element in Java

```
Function<Tuple2<String, String>, Boolean> longWordFilter =  
    new Function<Tuple2<String, String>, Boolean>() {  
        public Boolean call(Tuple2<String, String> keyValue) {  
            return (keyValue._2().length() < 20);  
        }  
    };  
JavaPairRDD<String, String> result = pairs.filter(longWordFilter);
```

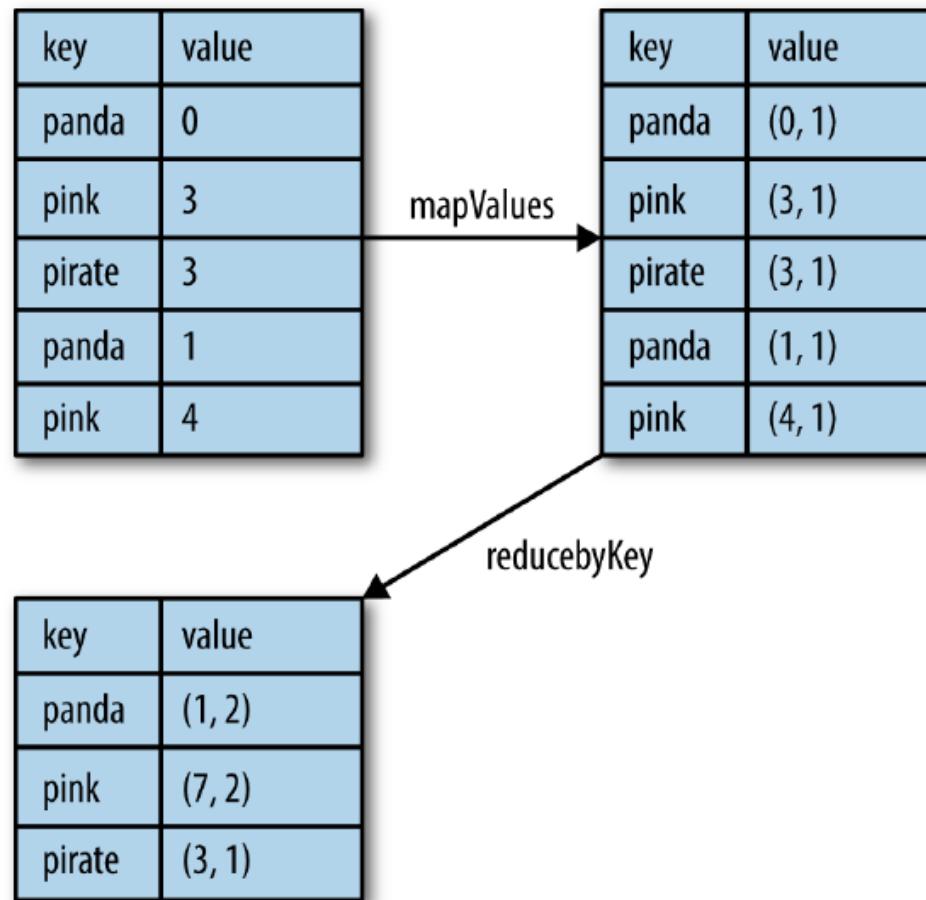

Examples of Per-key Averaging

Example 4-7. Per-key average with `reduceByKey()` and `mapValues()` in Python

```
rdd.mapValues(lambda x: (x, 1)).reduceByKey(lambda x, y: (x[0] + y[0], x[1] + y[1]))
```

Example 4-8. Per-key average with `reduceByKey()` and `mapValues()` in Scala

```
rdd.mapValues(x => (x, 1)).reduceByKey((x, y) => (x._1 + y._1, x._2 + y._2))
```

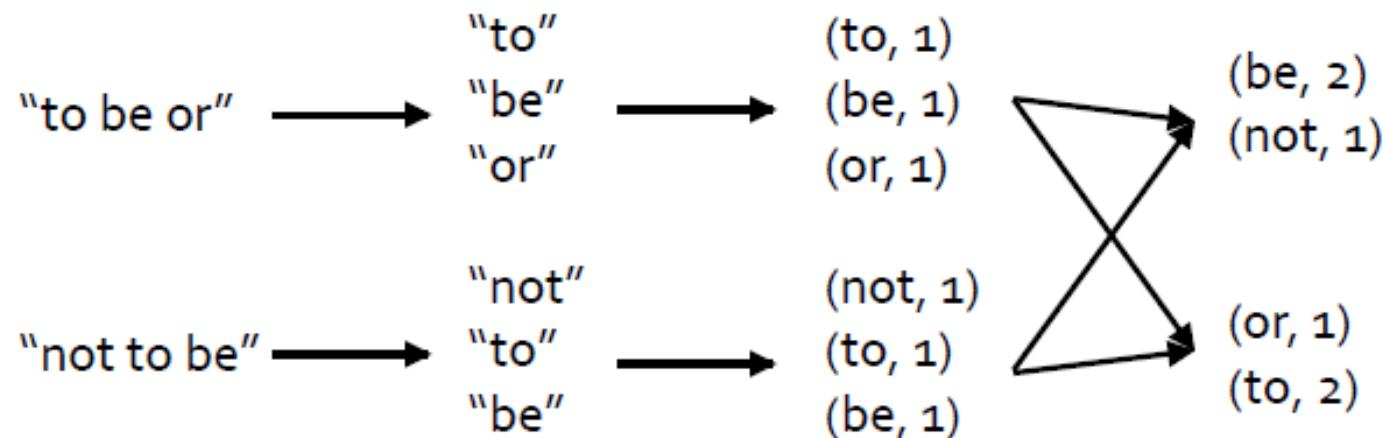

The Word Count Example in Python or Scala

Example 4-9. Word count in Python

```
rdd = sc.textFile("s3://...")  
words = rdd.flatMap(lambda x: x.split(" "))  
result = words.map(lambda x: (x, 1)).reduceByKey(lambda x, y: x + y)
```

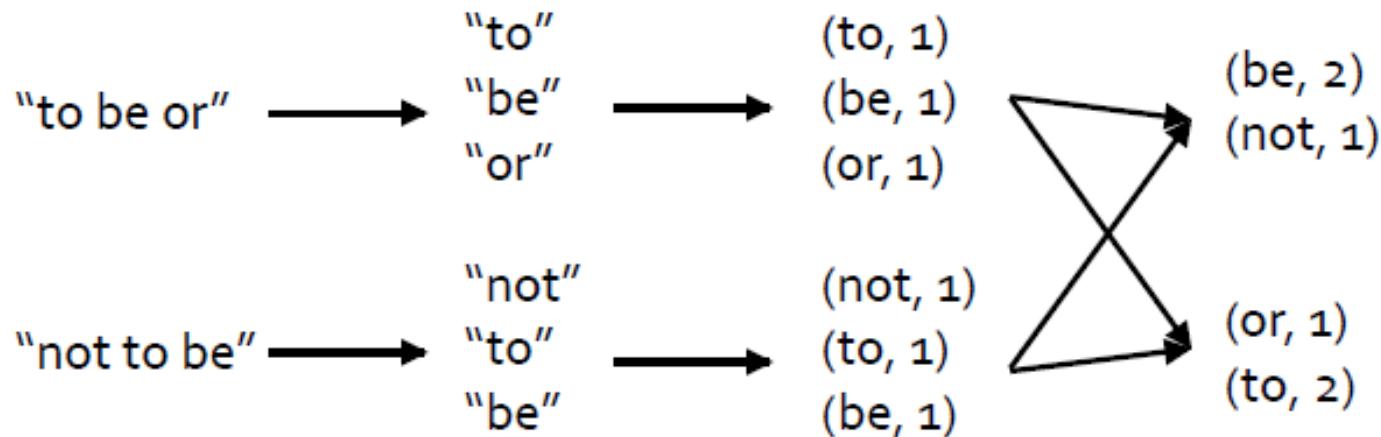

Example 4-10. Word count in Scala

```
val input = sc.textFile("s3://...")  
val words = input.flatMap(x => x.split(" "))  
val result = words.map(x => (x, 1)).reduceByKey((x, y) => x + y)
```

The Word Count Example (w/ Scala shorthand):

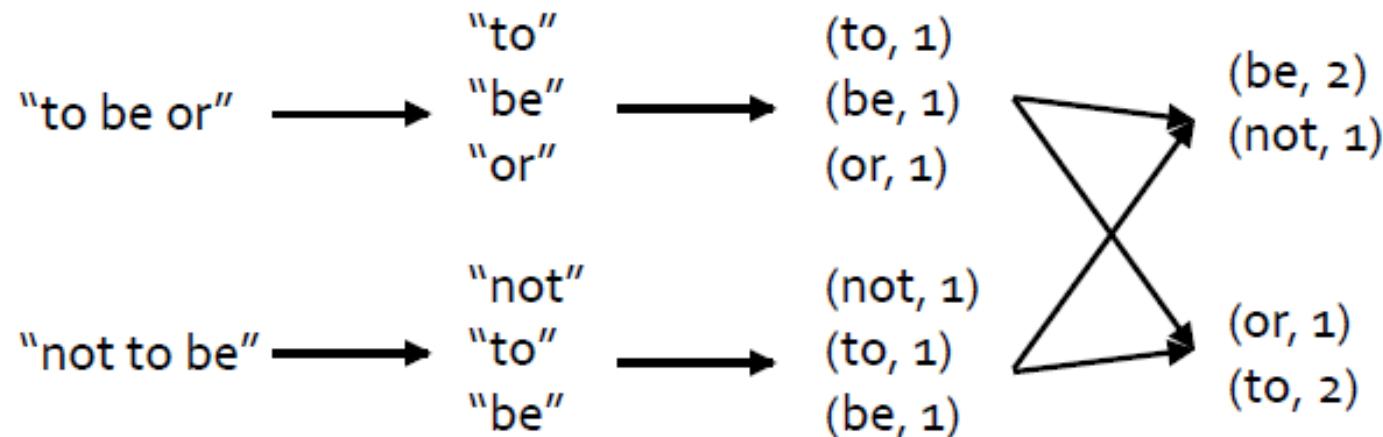

```
val lines = sc.textFile("hamlet.txt")  
  
val counts = lines.flatMap(line => line.split(" ")).  
               .map(word => (word, 1))  
               .reduceByKey(_ + _)
```

The Word Count Example in Java

Example 4-11. Word count in Java

```
JavaRDD<String> input = sc.textFile("s3://...")  
JavaRDD<String> words = rdd.flatMap(new FlatMapFunction<String, String>() {  
    public Iterable<String> call(String x) { return Arrays.asList(x.split(" ")); }  
});  
JavaPairRDD<String, Integer> result = words.mapToPair(  
    new PairFunction<String, String, Integer>() {  
        public Tuple2<String, Integer> call(String x) { return new Tuple2(x, 1); }  
    }).reduceByKey(  
    new Function2<Integer, Integer, Integer>() {  
        public Integer call(Integer a, Integer b) { return a + b; }  
    });
```

A Complete Example of Word-Count w/ Spark

```
1 public class WordCount {
2     public static class TokenizerMapper
3         extends Mapper<Object, Text, Text, IntWritable> {
4
5     private final static IntWritable one = new IntWritable(1);
6     private Text word = new Text();
7
8     public void map(Object key, Text value, Context context
9                     throws IOException, InterruptedException {
10        StringTokenizer itr = new StringTokenizer(value.toString());
11        while (itr.hasMoreTokens()) {
12            word.set(itr.nextToken());
13            context.write(word, one);
14        }
15    }
16}
17
18 public static class IntSumReducer
19     extends Reducer<Text,IntWritable,Text,IntWritable> {
20     private IntWritable result = new IntWritable();
21
22     public void reduce(Text key, Iterable<IntWritable> values,
23                        Context context
24                        throws IOException, InterruptedException {
25         int sum = 0;
26         for (IntWritable val : values) {
27             sum += val.get();
28         }
29         result.set(sum);
30         context.write(key, result);
31     }
32 }
33
34 public static void main(String[] args) throws Exception {
35     Configuration conf = new Configuration();
36     String[] otherArgs = new GenericOptionsParser(conf, args).getRemainingArgs();
37     if (otherArgs.length < 2) {
38         System.err.println("Usage: wordcount <in> [<in>...] <out>");
39         System.exit(2);
40     }
41     Job job = new Job(conf, "word count");
42     job.setJarByClass(WordCount.class);
43     job.setMapperClass(TokenizerMapper.class);
44     job.setCombinerClass(IntSumReducer.class);
45     job.setReducerClass(IntSumReducer.class);
46     job.setOutputKeyClass(Text.class);
47     job.setOutputValueClass(IntWritable.class);
48     for (int i = 0; i < otherArgs.length - 1; ++i) {
49         FileInputFormat.addInputPath(job, new Path(otherArgs[i]));
50     }
51     FileOutputFormat.setOutputPath(job,
52         new Path(otherArgs[otherArgs.length - 1]));
53     System.exit(job.waitForCompletion(true) ? 0 : 1);
54 }
55 }
```

```
1 val f = sc.textFile(inputPath)
2 val w = f.flatMap(l => l.split(" ")).map(word => (word, 1)).cache()
3 w.reduceByKey(_ + _).saveAsText(outputPath)
```

WordCount in 3 lines of Spark

WordCount in 50+ lines of Java MR

Spark 90

Changing the Persistence of RDD

- By default, RDDs are lazy and ephemeral.
- User can alter the persistence of an RDD through two actions:
 - Cache action: By calling the persist() method, user provides the **hints** that the RDD should be kept in memory after the first time it is computed, because it will be reused.
 - Save action: evaluates the dataset and writes it to a distributed filesystem such as HDFS
- Spark keeps persistent RDDs in memory by default, but it can spill them to disk if there is not enough RAM.
- Users can set a persistence priority on each RDD to specify which in-memory data should spill to disk first.

Memory Management in Spark

Spark provides three options for persist RDDs:

- (1) In-memory storage as deserialized Java Objects
 - >> fastest, JVM can access RDD natively
- (2) In-memory storage as serialized data
 - >> space limited, choose another efficient representation, lower performance
- (3) On-disk storage
 - >> RDD too large to keep in memory, and costly to recompute

Persistence Levels in Spark

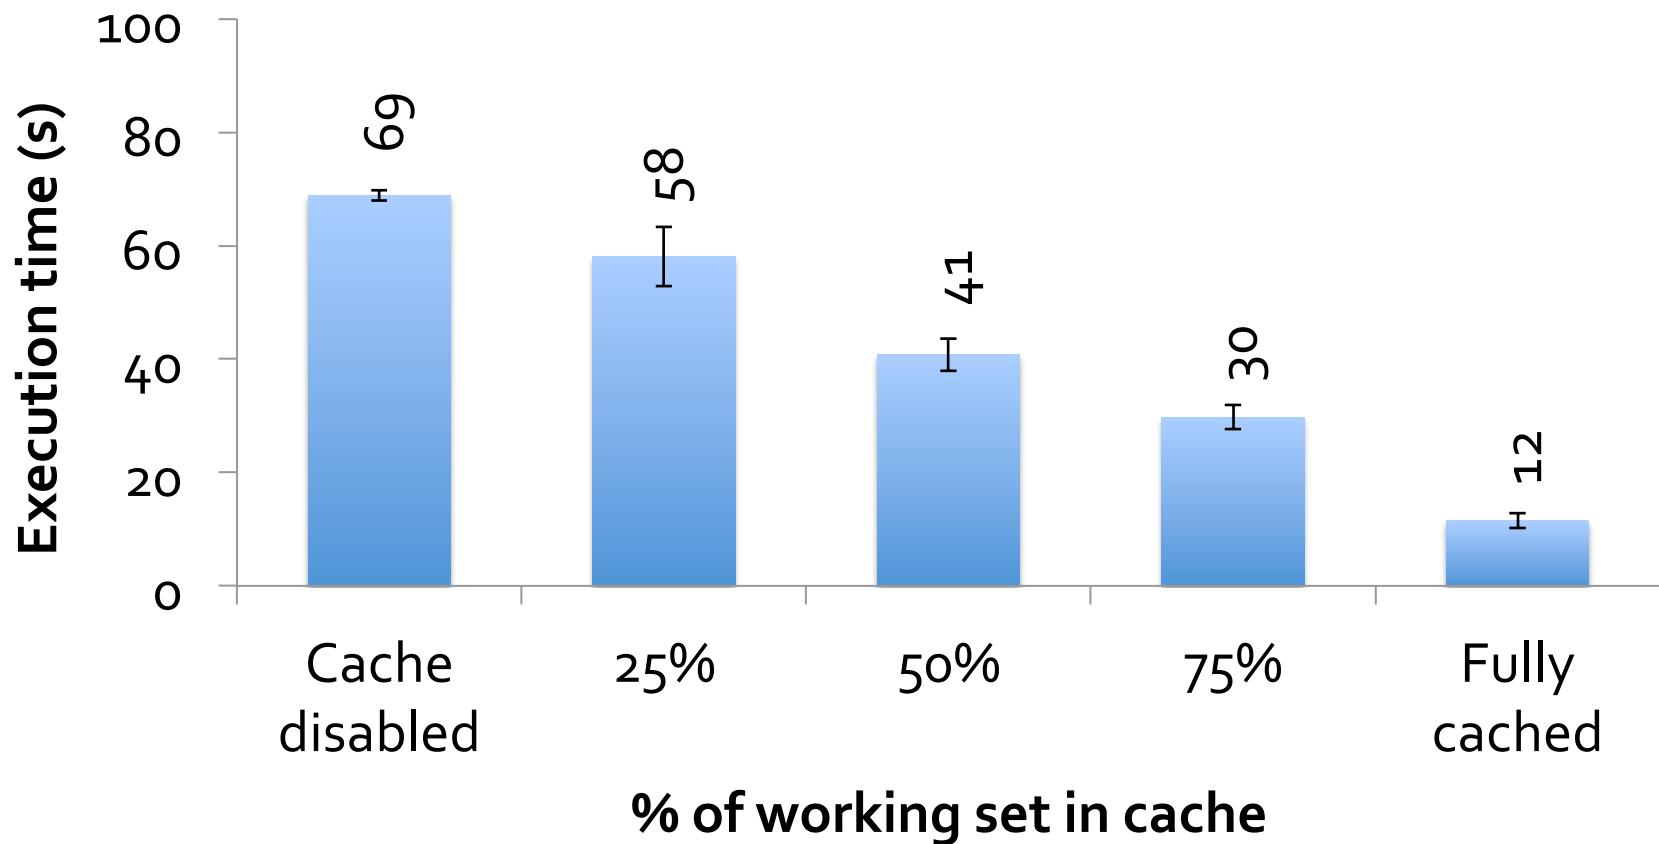

Table 3-6. Persistence levels from `org.apache.spark.storage.StorageLevel` and `pyspark.StorageLevel`; if desired we can replicate the data on two machines by adding `_2` to the end of the storage level

Level	Space used	CPU time	In memory	On disk	Comments
MEMORY_ONLY	High	Low	Y	N	
MEMORY_ONLY_SER	Low	High	Y	N	
MEMORY_AND_DISK	High	Medium	Some	Some	Spills to disk if there is too much data to fit in memory.
MEMORY_AND_DISK_SER	Low	High	Some	Some	Spills to disk if there is too much data to fit in memory. Stores serialized representation in memory.
DISK_ONLY	Low	High	N	Y	

Example 3-40. `persist()` in Scala

```
val result = input.map(x => x * x)
result.persist(StorageLevel.DISK_ONLY)
println(result.count())
println(result.collect().mkString(","))
```

Behavior with Less RAM

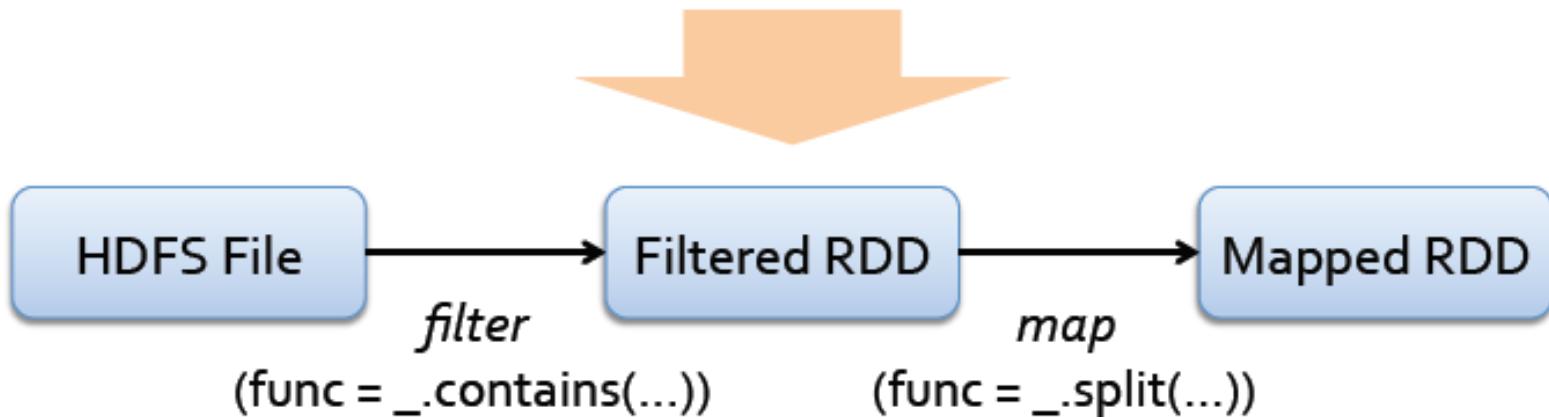

RDDs vs. Distributed Shared Memory

Aspect	RDDs	DSM
Reads	Coarse- or fine-grained	Fine-grained
Writes	Coarse-grained	Fine-grained
Consistency	Trivial(immutable)	Up to app / runtime
Fault recovery	Fine-grained and low-overhead using lineage	Requires checkpoints and program rollback
Straggler mitigation	Possible using backup tasks	Difficult
Work placement	Automatic based on data locality	Up to app (runtimes aim for transparency)
Behavior if not enough RAM	Similar to existing data flow systems	Poor performance(swapping ?)

RDD Fault Tolerance

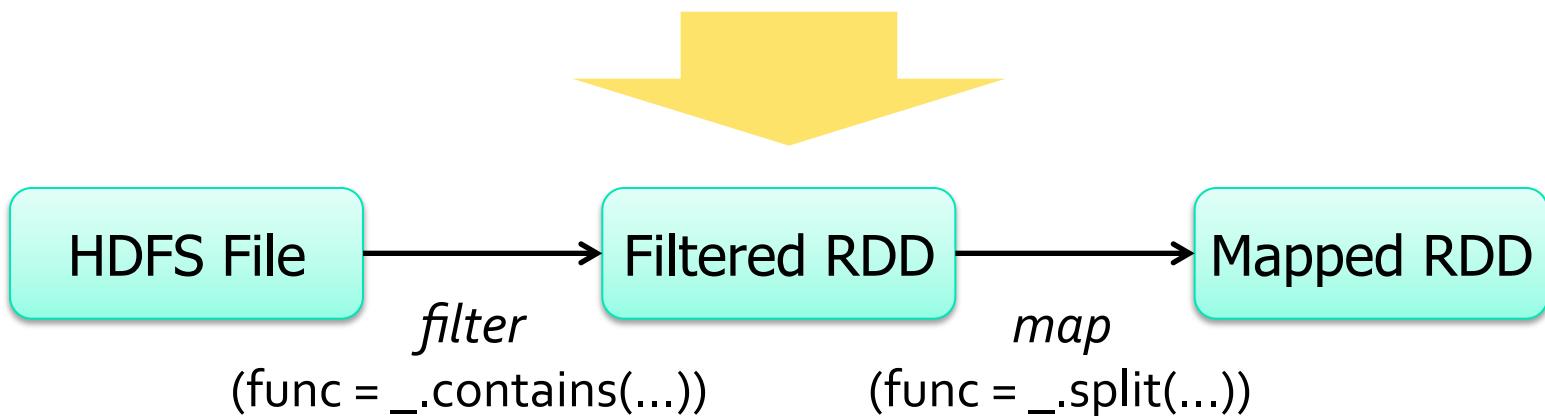

- An RDD has enough information about how it was derived from other datasets (aka its lineage).
 - RDD's Lineage info can be used to reconstruct lost partitions

Ex: `messages = textFile(...).filter(_.startswith("ERROR"))
 .map(_.split('\t'))(2)`

(Same Example in Python)

```
msgs = textFile.filter(lambda s: s.startswith("ERROR"))
                  .map(lambda s: s.split("\t")[2])
```

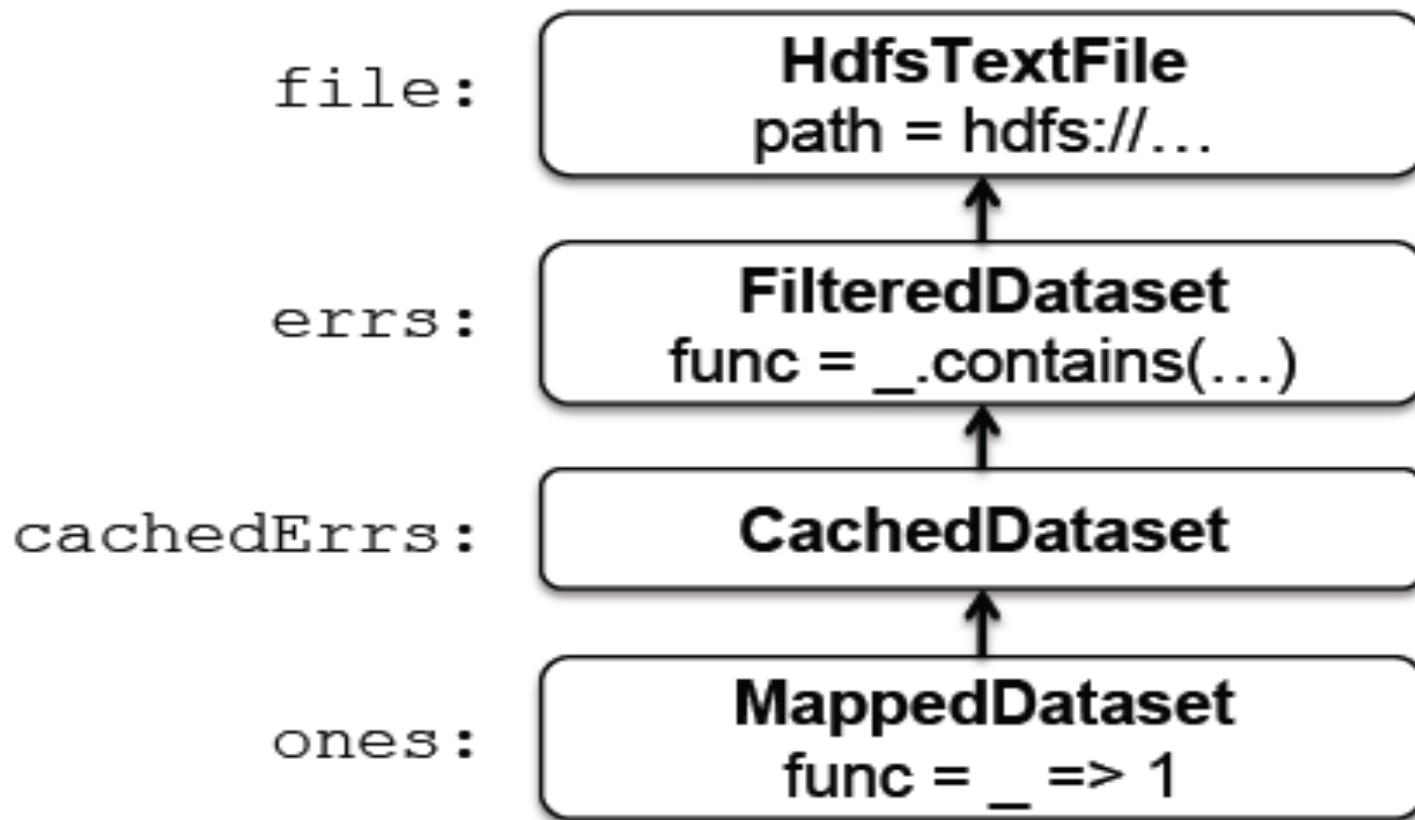

Example 2 of RDD

```
val file = spark.textFile("hdfs://...")  
val errs = file.filter(_.contains("ERROR"))  
val cachedErrs = errs.cache()  
val ones = cachedErrs.map(_ => 1)  
val count = ones.reduce(_+_)
```

- These datasets will be stored as a chain of objects capturing the lineage of each RDD. Each dataset object contains a pointer to its parent and information about how the parent was transformed.

Lineage Chain of Example2

Example 3 of RDD

```
lines = spark.textFile("hdfs://...")  
errors = lines.filter(_.startsWith("ERROR"))  
errors.persist()  
  
// Count errors mentioning MySQL:  
errors.filter(_.contains("MySQL")).count()  
  
// Return the time fields of errors mentioning  
// HDFS as an array (assuming time is field  
// number 3 in a tab-separated format):  
errors.filter(_.contains("HDFS"))  
    .map(_.split('\t')(3))  
    .collect()
```

Lineage Chain of Example 3

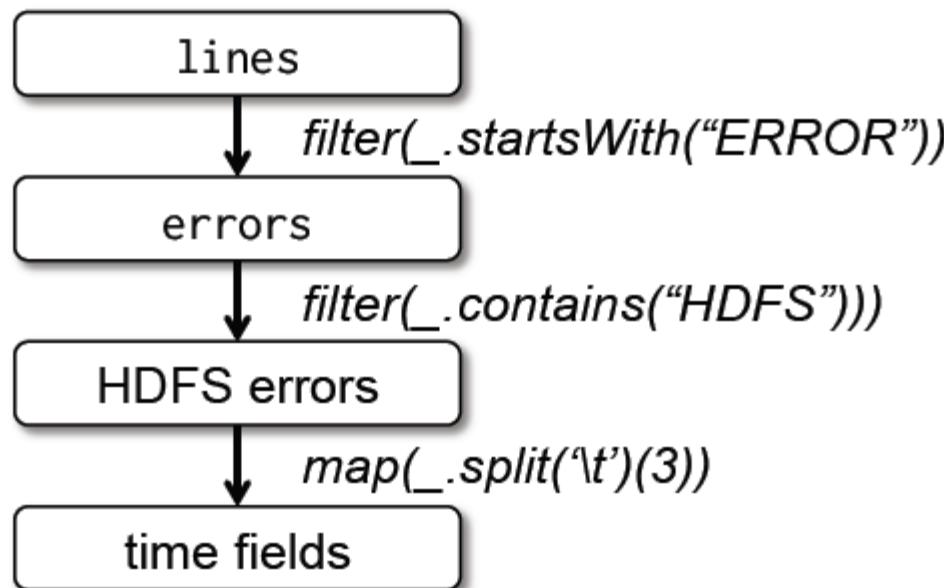

Figure 1: Lineage graph for the third query in our example. Boxes represent RDDs and arrows represent transformations.

What is an RDD ?

- A: Distributed Collection of Objects on disks
 - B: Distributed Collection of Objects in memory
 - C: Distributed Collection of Objects in Cassandra
-
- Answer: Could be any of the above.

What is an RDD ?

- Scientific Answer: RDD is an Interface !

1. Set of *partitions* (“splits” in Hadoop)
 2. List of *dependencies* on parent RDDs
 3. Function to *compute* a partition
(as an Iterator) given its parent(s)
 4. (Optional) *partitioner* (hash, range)
 5. (Optional) *preferred location(s)*
for each partition
-
- The diagram illustrates the components of an RDD. A vertical blue bracket on the right side groups the first three items (1, 2, 3) under the label "lineage". Another vertical blue bracket on the right side groups the last two items (4, 5) under the label "optimized execution".

Interface used to represent RDDs

Operation	Meaning
<i>partitions()</i>	Return a list of partition objects
<i>preferredLocations(p)</i>	List nodes where partition p can be accessed faster due to data locality
<i>dependencies()</i>	Return a list of dependencies
<i>iterator(p, parentIters)</i>	Compute the elements of partition p given iterators for its parent partitions
<i>partitioner()</i>	Return metadata specifying whether the RDD is hash/range partitioned

Example: A HadoopRDD

partitions = one per HDFS block

dependencies = none

`compute(part)` = read corresponding block

`preferredLocations(part)` = HDFS block location

partitioner = none

Example: A Filtered RDD

`partitions` = same as parent RDD

`dependencies` = “one-to-one” on parent

`compute(part)` = compute parent and filter it

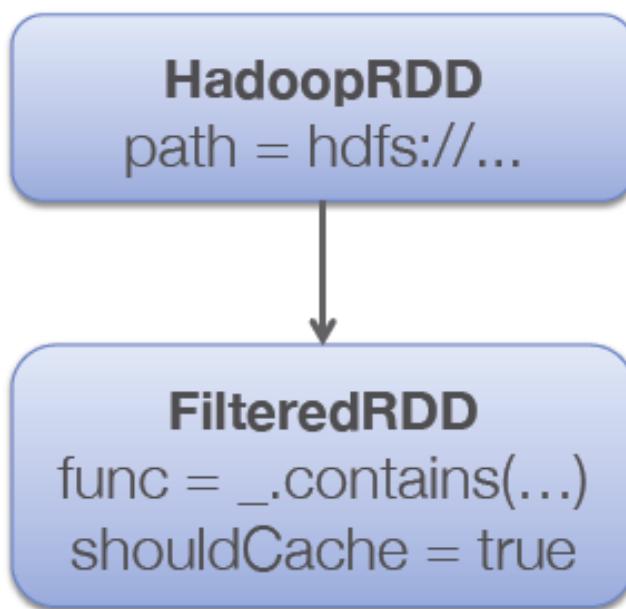

`preferredLocations(part)` = none (ask parent)

`partitioner` = none

RDD Graph (DAG of tasks)

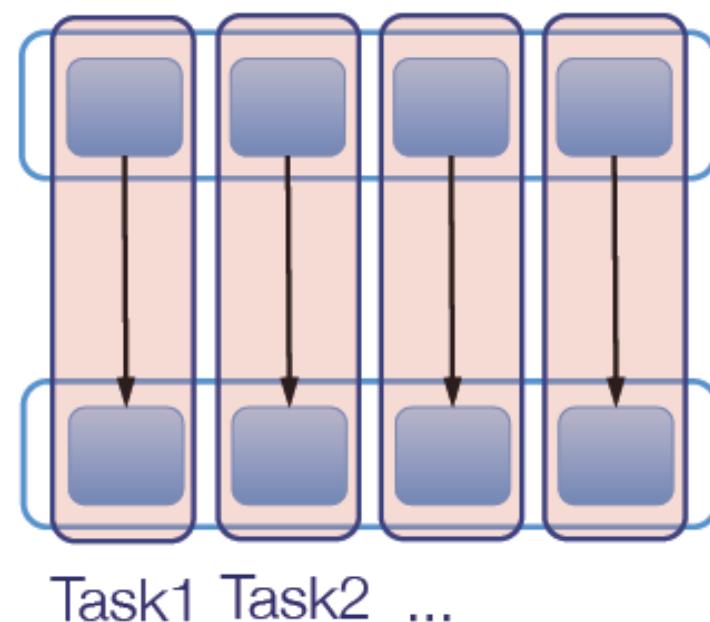

Dataset-level view:

file:

errors:

Partition-level view:

Example: A Joined RDD

partitions = one per reduce task

dependencies = “shuffle” on each parent

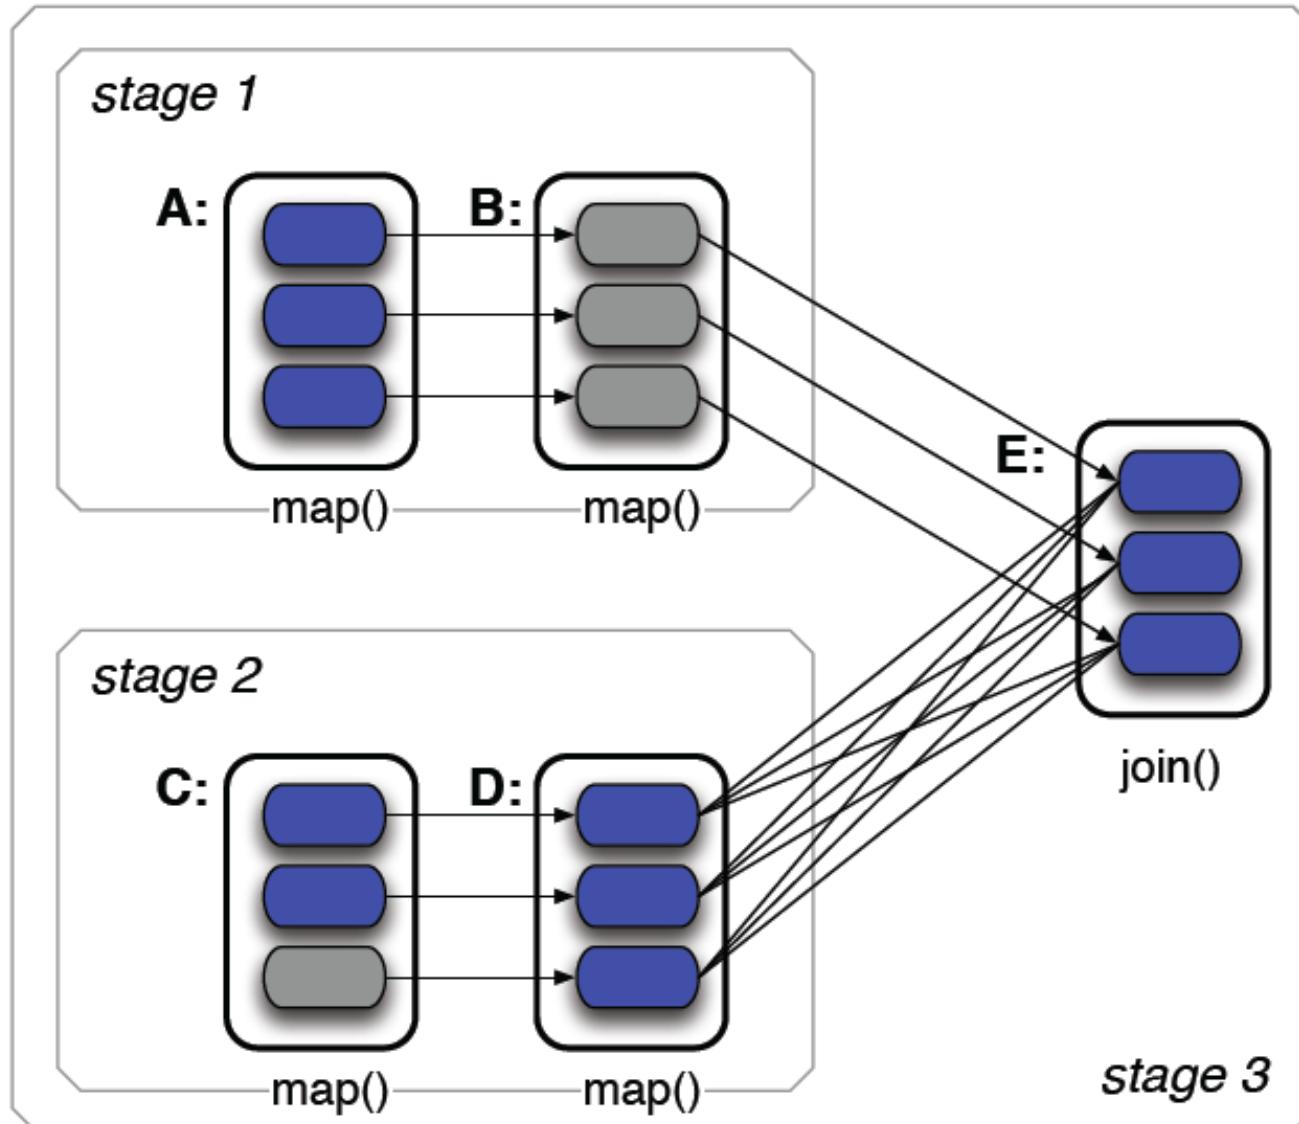

compute(*partition*) = read and join shuffled data

preferredLocations(*part*) = none

partitioner = HashPartitioner(numTasks)

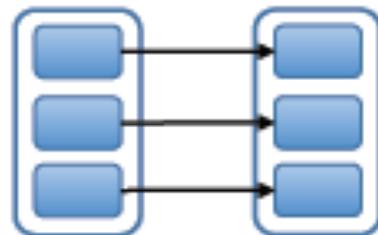

Spark will now know
this data is hashed!

Example: Join and its Operator Graph

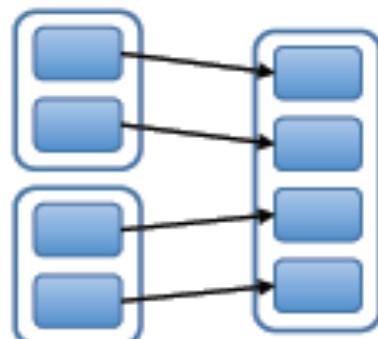

RDD Dependency Types

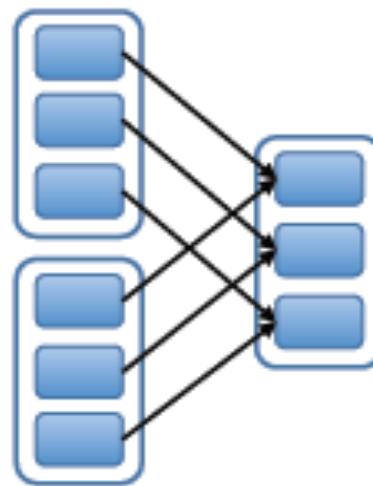

Narrow Dependencies:

map, filter

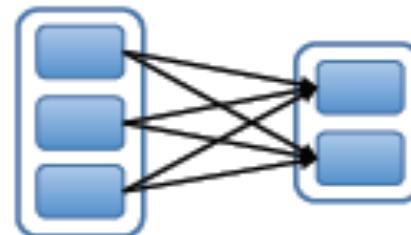

union

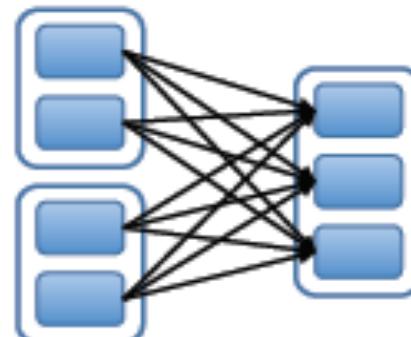

join with inputs
co-partitioned

Wide Dependencies:

groupByKey

join with inputs not
co-partitioned

Each box is an RDD, with partitions shown as shaded rectangles

Dependencies between RDDs(1)

- Narrow Dependencies: each partition of the parent RDD is used by at most one partition of the child RDD(1:1). Map leads to a narrow dependency.
- Wide Dependencies: multiple child partitions may depend on it(1:N). Join leads to wide dependencies.

Dependencies between RDDs(2)

- Narrow dependencies allow for **pipelined** execution on one cluster node, which can compute all the parent partitions. For example, one can apply a map followed by a filter on an element-by-element basis.
- Wide dependencies require data from all parent partitions to be available and to be shuffled across the nodes using a MapReduce like operation.
- Recovery after a node failure is more efficient with a narrow dependency than the ones with wide dependency.

Advanced Features

- Controllable partitioning
 - Speed up joins against a dataset
- Controllable storage formats
 - Keep data serialized for efficiency, replicate to multiple nodes, cache on disk
- Shared variables: broadcasts, accumulators

Shared Variables

- Programmers invoke operations like map, filter and reduce by passing closures (functions) to Spark. Normally, when Spark runs a closure on a worker node, these variables are copied to the worker.
- However, Spark also lets programmers create two restricted types of shared variables to support two simple but common usage patterns.

Broadcast Variables

- When one creates a broadcast variable b with a value v , v is saved to a file in a shared file system. The serialized form of b is a path to this file. When b 's value is queried on a worker node, Spark first checks whether v is in a local cache, and reads it from the file system if it isn't.

Accumulators

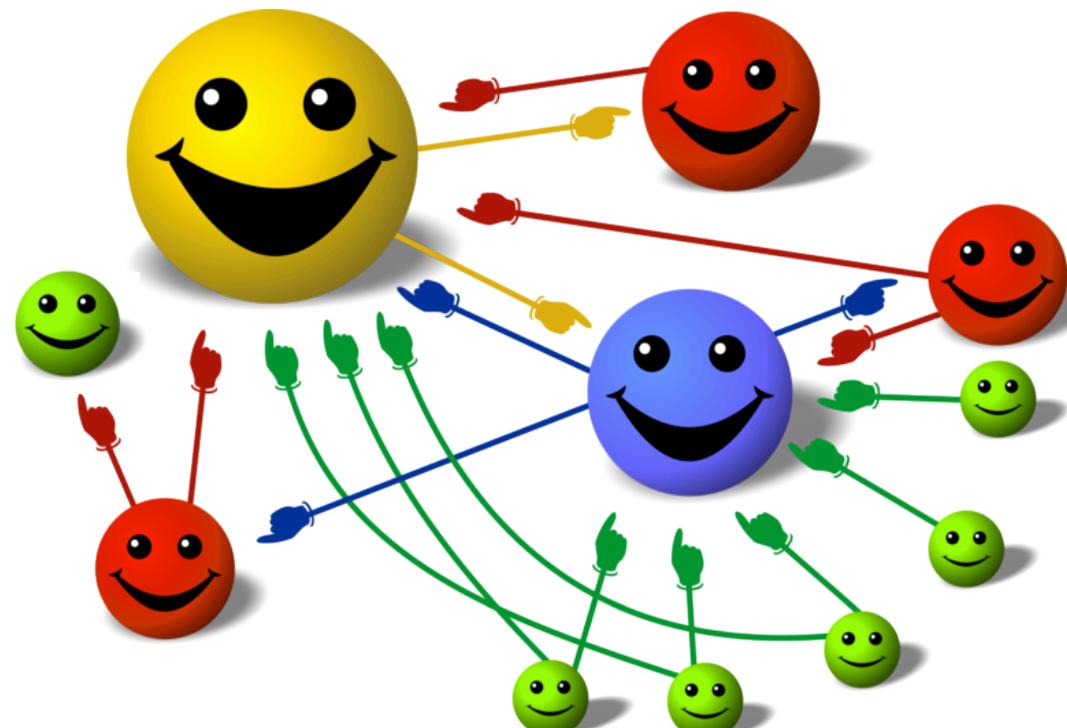

- Each accumulator is given a unique ID when it is created. When the accumulator is saved, its serialized form contains its ID and the “zero” value for its type.
- On the workers, a separate copy of the accumulator is created for each thread that runs a task using thread-local variables, and is reset to zero when a task begins. After each task runs, the worker sends a message to the driver program containing the updates it made to various accumulators.

A More Sophisticated Example: Computing PageRank w/ Spark

- Good example of a more complex algorithm
 - Multiple stages of map & reduce
- Benefits from Spark's in-memory caching
 - Multiple iterations over the same data
- Demonstrating the Importance of Controlling the Partitioning of RDDs for Performance Optimization

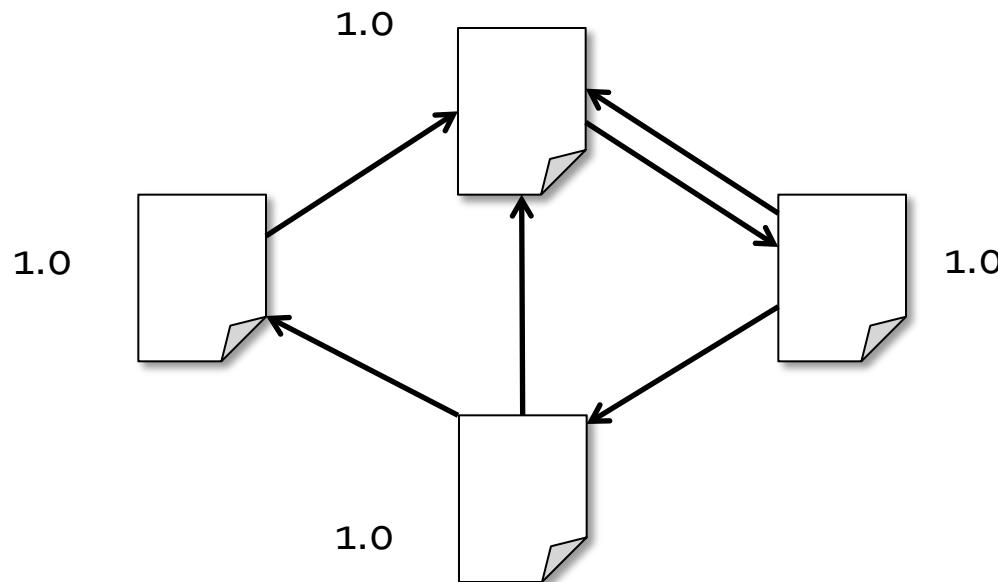

Basic Idea

- Give pages ranks (scores) based on links to them
 - Links from many pages → high rank
 - Link from a high-rank page → high rank

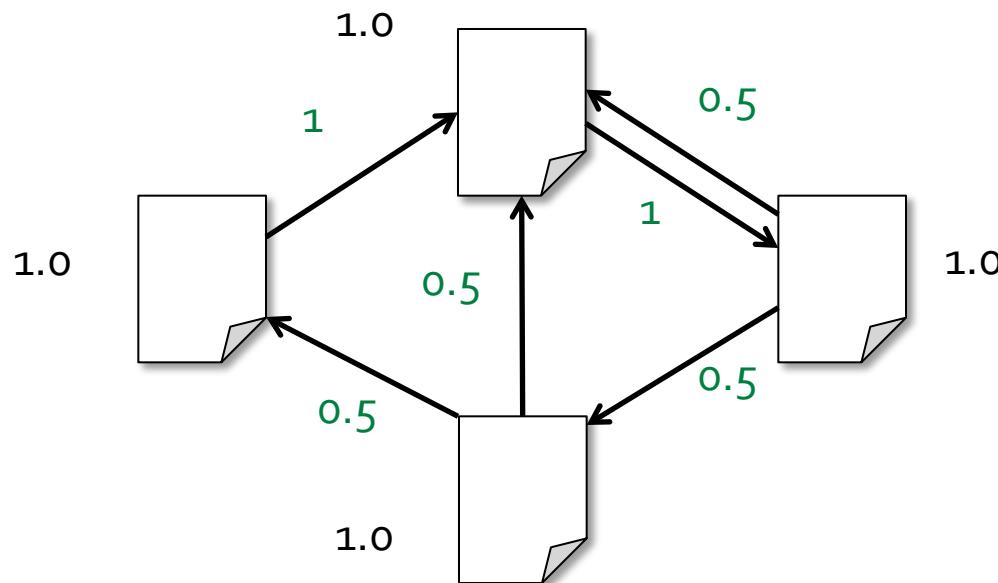

Algorithm

1. Start each page at a rank of 1
2. On each iteration, have page p contribute $\text{rank}_p / |\text{neighbors}_p|$ to its neighbors
3. Set each page's rank to $0.15 + 0.85 \times \text{contribs}$

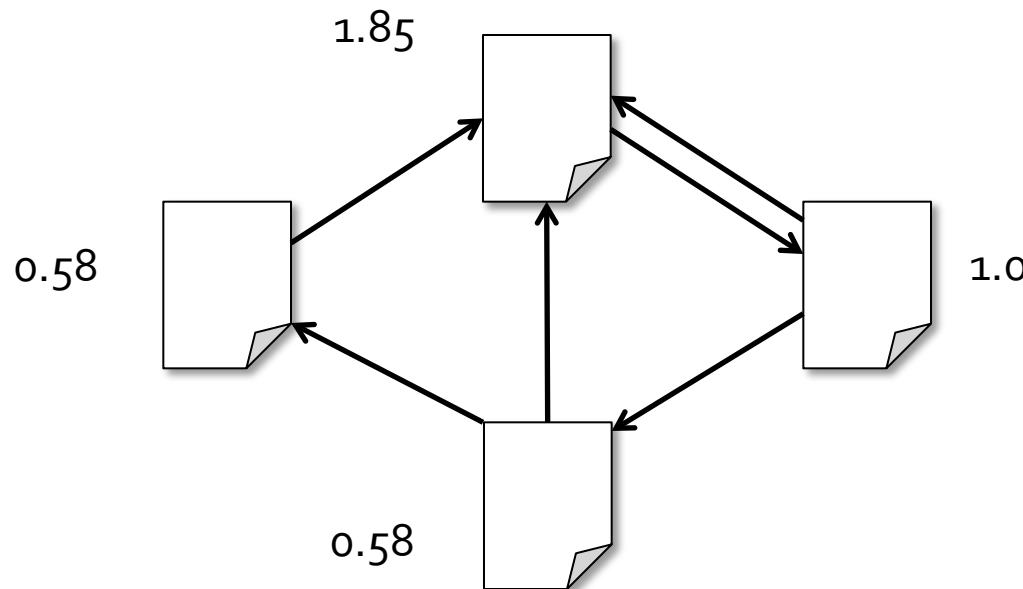

Algorithm

1. Start each page at a rank of 1
2. On each iteration, have page p contribute $\text{rank}_p / |\text{neighbors}_p|$ to its neighbors
3. Set each page's rank to $0.15 + 0.85 \times \text{contribs}$

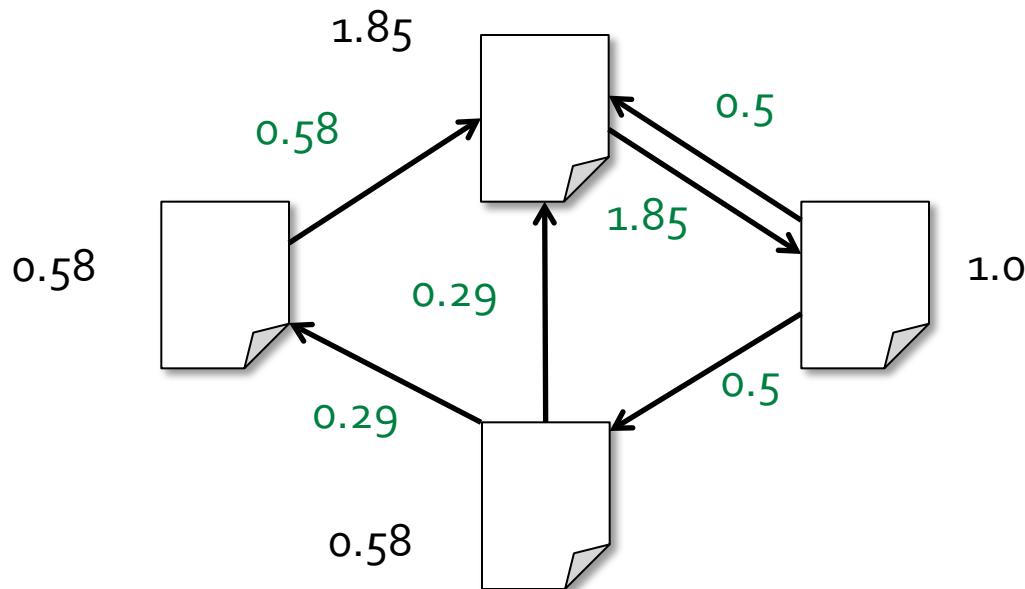

Algorithm

1. Start each page at a rank of 1
2. On each iteration, have page p contribute $\text{rank}_p / |\text{neighbors}_p|$ to its neighbors
3. Set each page's rank to $0.15 + 0.85 \times \text{contribs}$

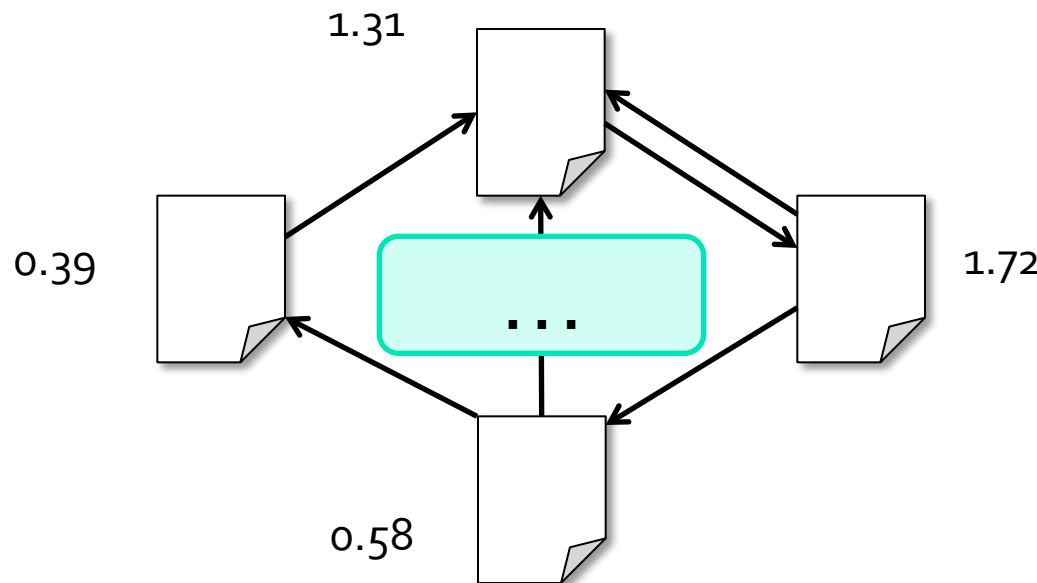

Algorithm

1. Start each page at a rank of 1
2. On each iteration, have page p contribute $\text{rank}_p / |\text{neighbors}_p|$ to its neighbors
3. Set each page's rank to $0.15 + 0.85 \times \text{contribs}$

Algorithm

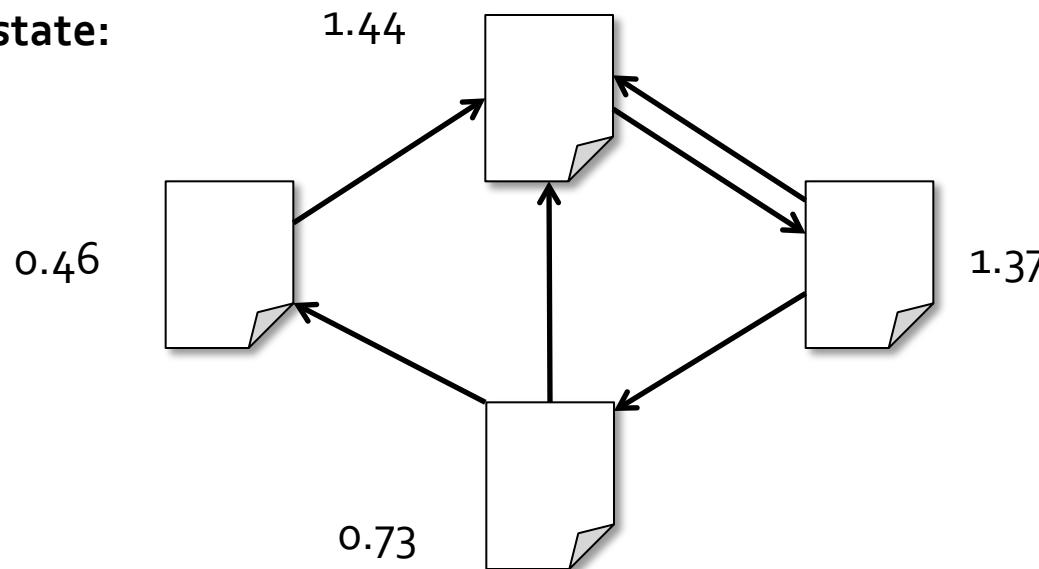

1. Start each page at a rank of 1
2. On each iteration, have page p contribute $\text{rank}_p / |\text{neighbors}_p|$ to its neighbors
3. Set each page's rank to $0.15 + 0.85 \times \text{contribs}$

Algorithm

1. Start each page at a rank of 1
2. On each iteration, have page p contribute $\text{rank}_p / |\text{neighbors}_p|$ to its neighbors
3. Set each page's rank to $0.15 + 0.85 \times \text{contribs}$

Final state:

Naïve Implementation of PageRank in Spark (in Scala)

1. Start each page at a rank of 1
2. On each iteration, have page p contribute $\text{rank}_p / |\text{neighbors}_p|$ to its neighbors
3. Set each page's rank to $0.15 + 0.85 \times \text{contribs}$

```
val links = // RDD of (url, neighbors) pairs
var ranks = // RDD of (url, rank) pairs

for (i <- 1 to ITERATIONS) {
    val contribs = links.join(ranks).flatMap {
        case (url, (links, rank)) =>
            links.map(dest => (dest, rank/links.size))
    }
    ranks = contribs.reduceByKey(_ + _).mapValues(.15 + .85*_)
}
```

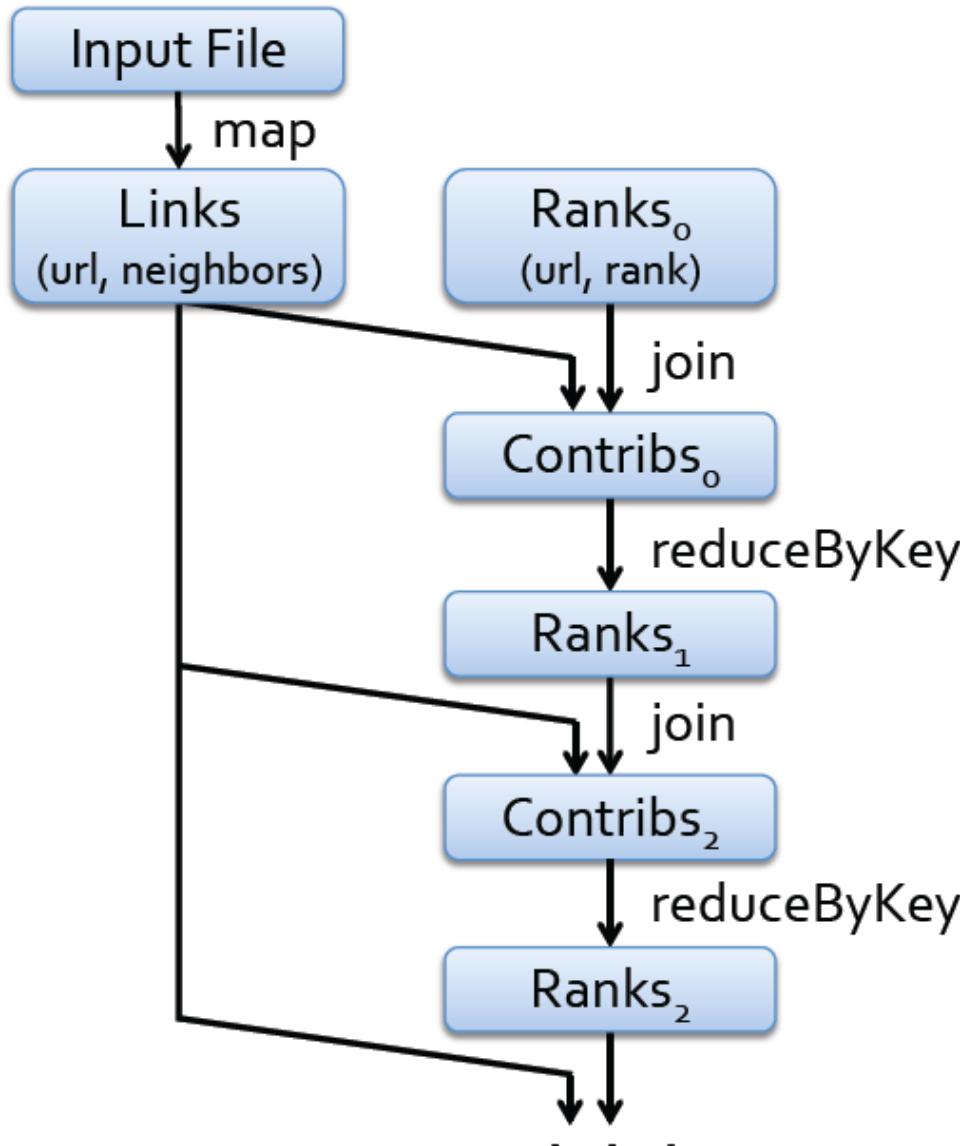

Naïve Implementation of PageRank in Spark (in Scala)

```
val sc = new SparkContext("local", "PageRank", sparkHome,  
                         Seq("pagerank.jar"))

val links = // Load RDD of (url, neighbors) pairs  
var ranks = // Load RDD of (url, rank) pairs

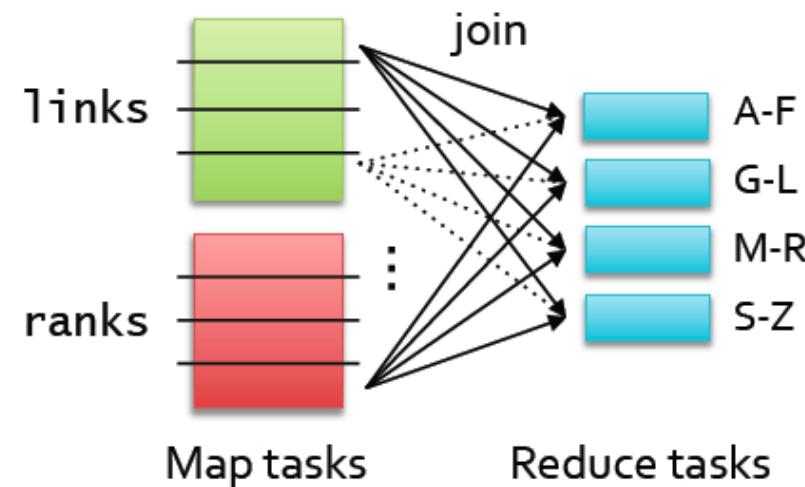

for (i <- 1 to ITERATIONS) {  
    val contribs = links.join(ranks).flatMap {  
        case (url, (links, rank)) =>  
            links.map(dest => (dest, rank/links.size))  
    }  
    ranks = contribs.reduceByKey(_ + _)  
          .mapValues(0.15 + 0.85 * _)  
}  
ranks.saveAsTextFile(...)
```

Execution of the Naïve Implementation of PageRank in Spark

Links and ranks are repeatedly joined

Each join requires a full shuffle over the network
» Hash both onto same nodes

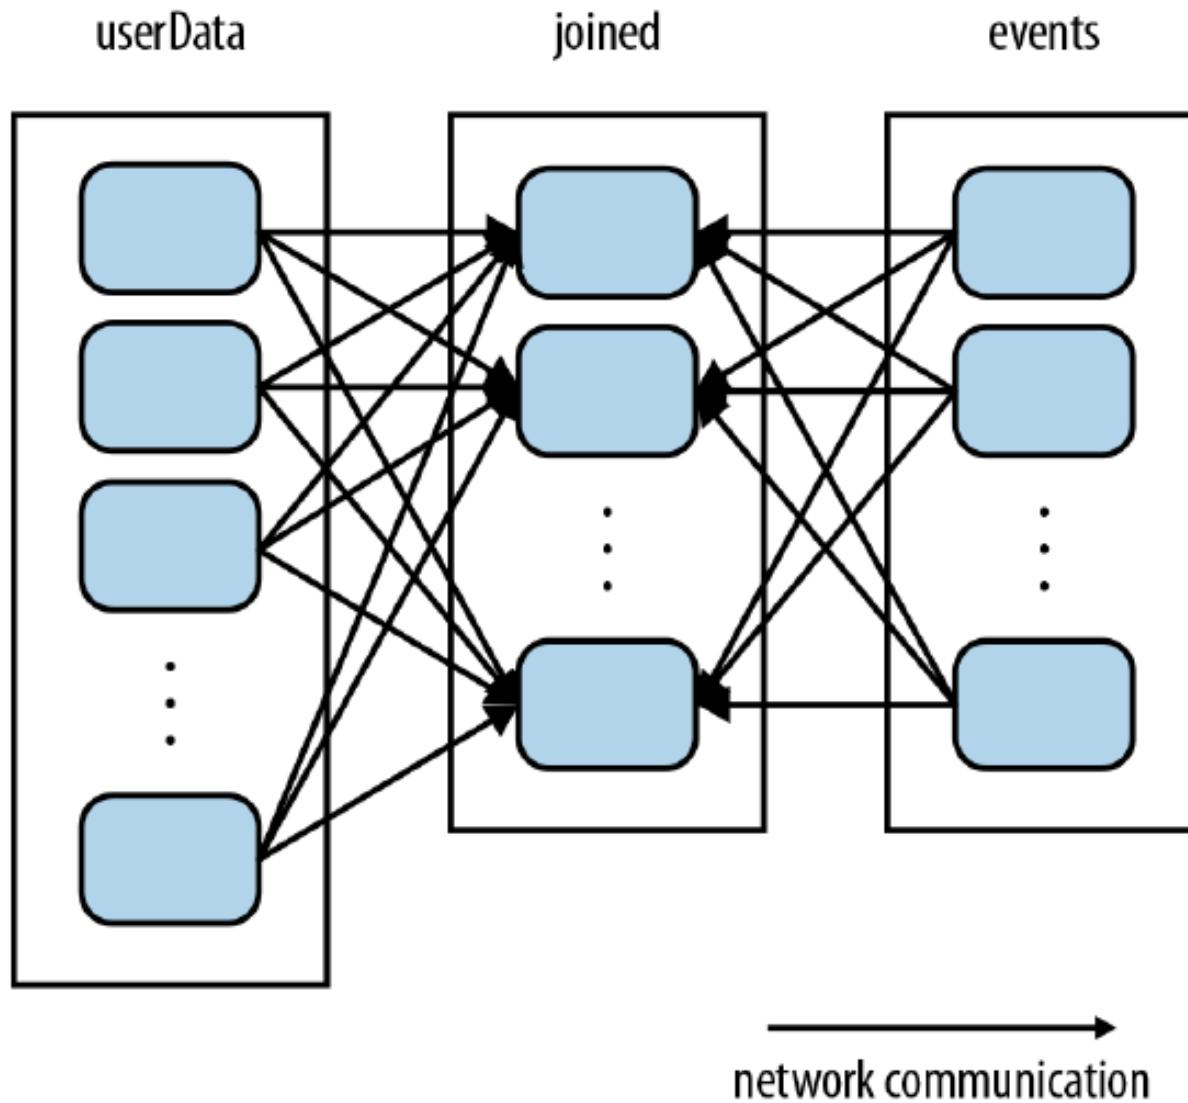

An Important (Optimization) Tool: Control the Partitioning of RDDs across different nodes

Pre-partition the links RDD so that links for URLs with the same hash code are on the same node

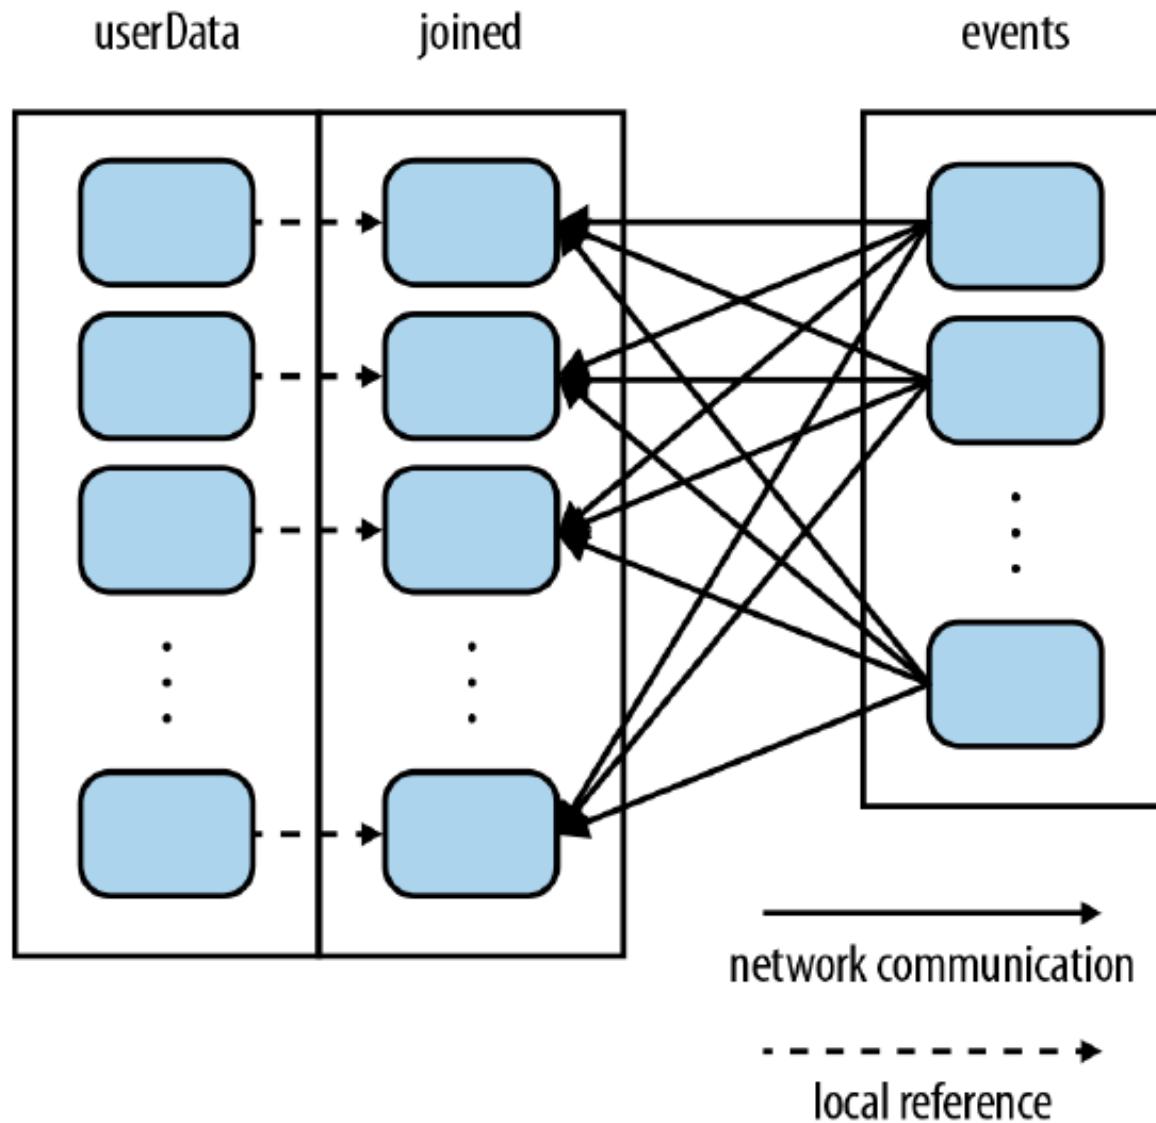

```
val ranks = // RDD of (url, rank) pairs
val links = sc.textFile(...).map(...)
    .partitionBy(new HashPartitioner(8))

for (i <- 1 to ITERATIONS) {
  ranks = links.join(ranks).flatMap {
    (url, (links, rank)) =>
      links.map(dest => (dest, rank/links.size))
  }.reduceByKey(_ + _)
  .mapValues(0.15 + 0.85 * _)
}
```

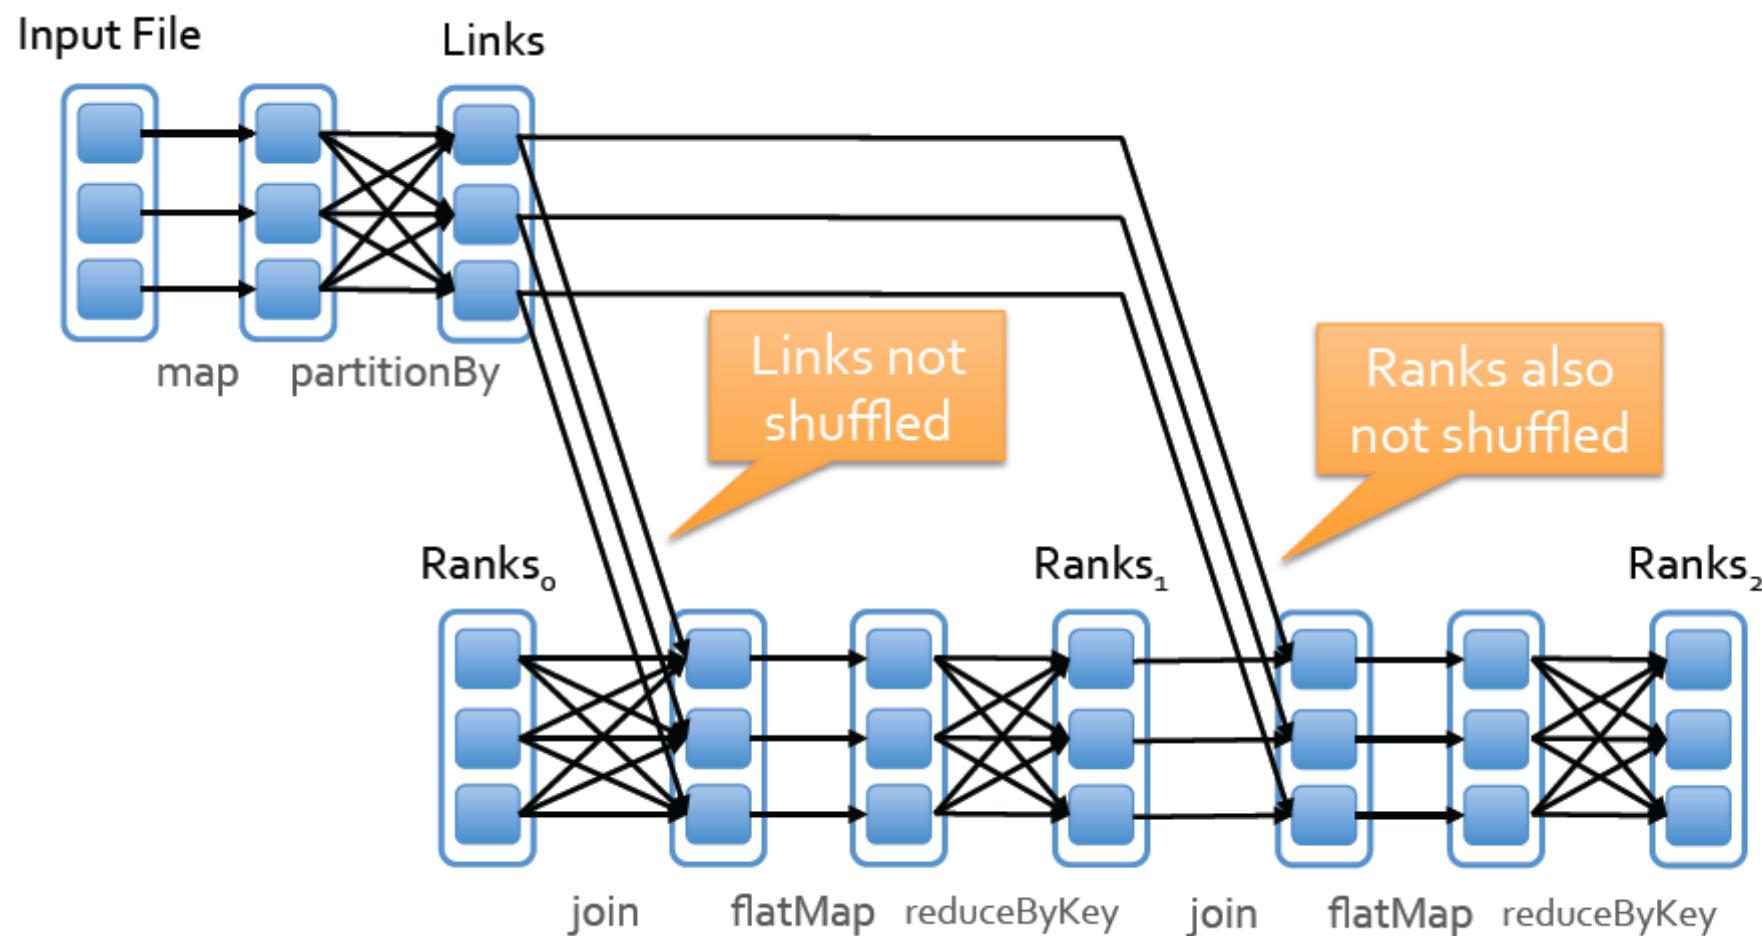

Join without using partitionBy

Join after using partitionBy

Execution Flow of this NEW Implementation of PageRank in Spark

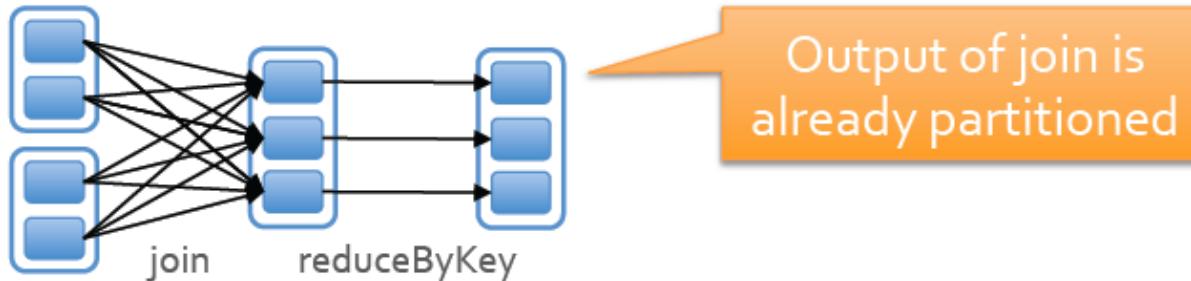

How does it work ?

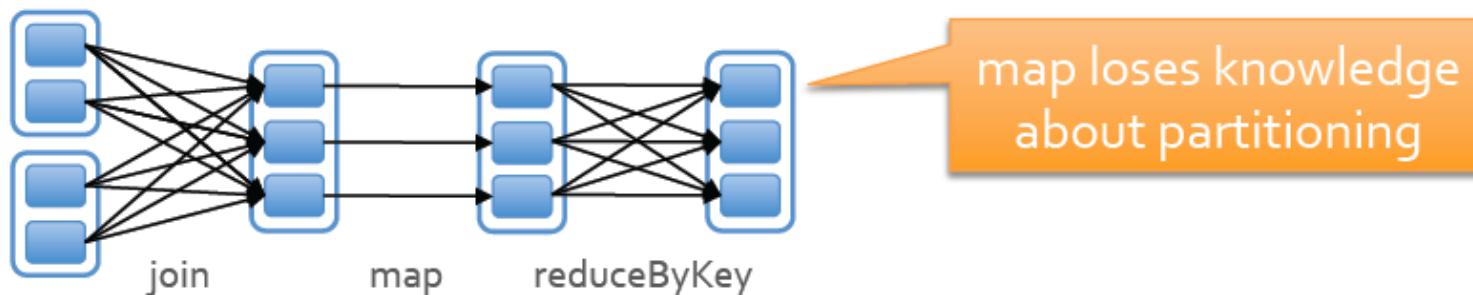

- Each RDD has an **OPTIONAL** Partitioner object
- Any shuffle operation on an RDD with a Partitioner **will respect that** Partitioner
- Any shuffle operation on two RDDs will take on the Partitioner of one of them, if one is set ;
 - Otherwise, will use the HashPartitioner by default

Examples of RDD Partitioning

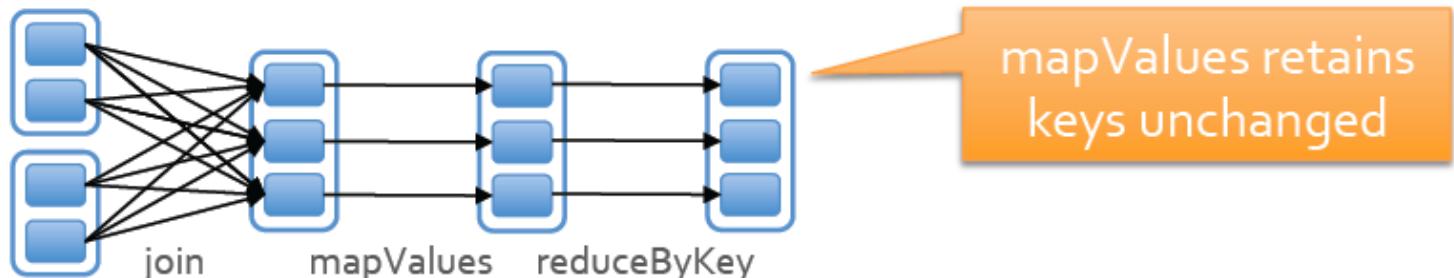

`pages.join(visits).reduceByKey(...)`

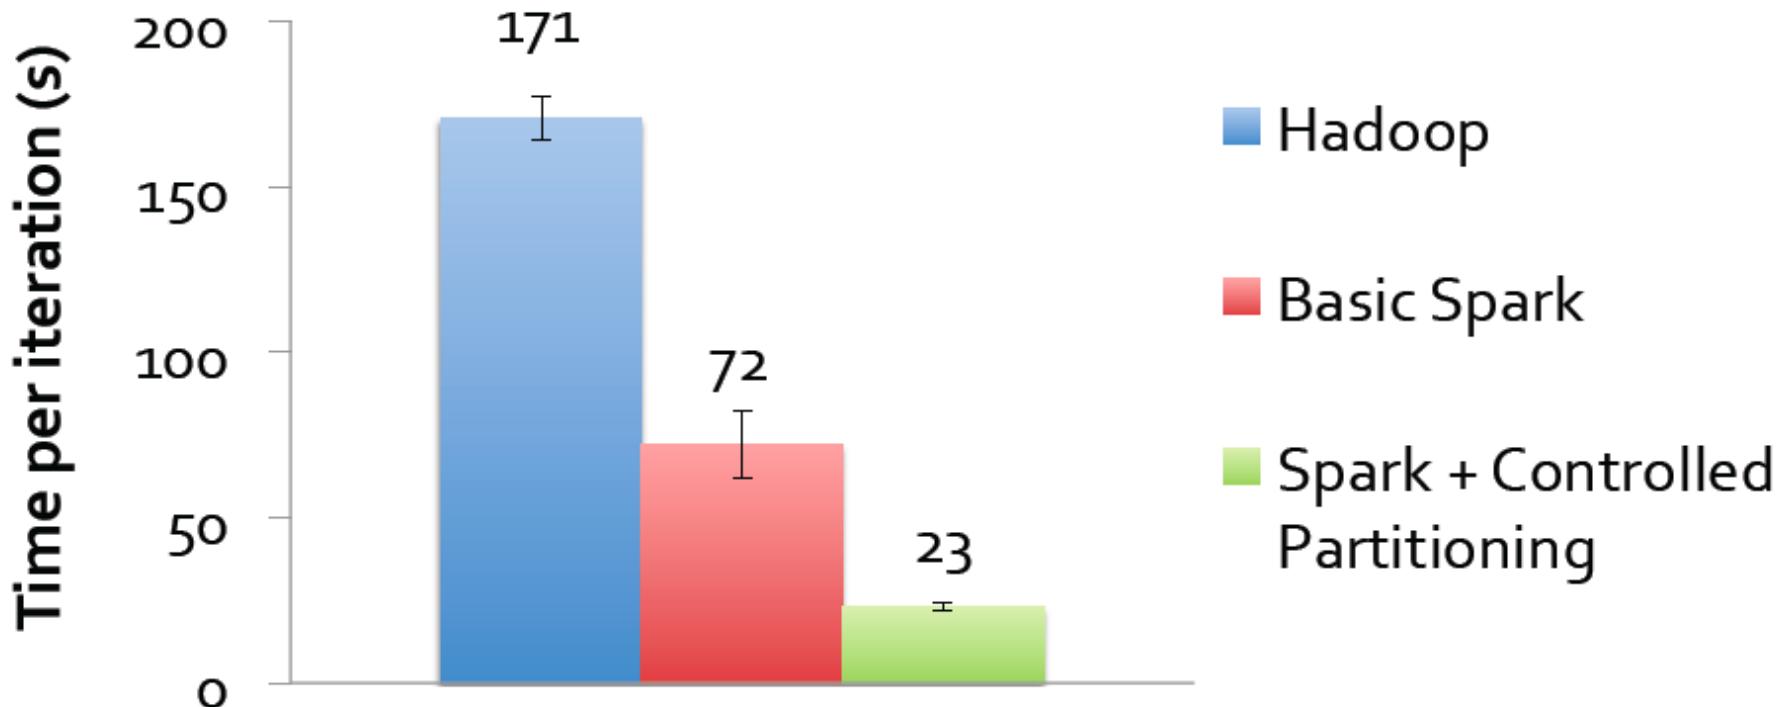

`pages.join(visits).map(...).reduceByKey(...)`

`pages.join(visits).mapValues(...).reduceByKey(...)`

PageRank Performance

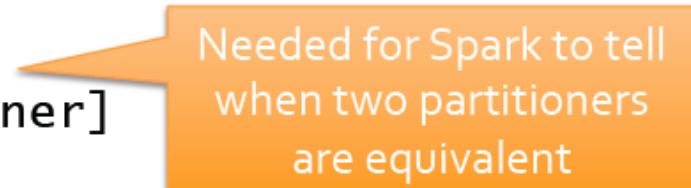

Why it helps so much: Links RDD is much bigger
in bytes than ranks!

How to Customized RDD Partitioning

Can define your own subclass of `Partitioner` to leverage domain-specific knowledge

Example: in PageRank, hash URLs by domain name

```
class DomainPartitioner extends Partitioner {  
    def numPartitions = 20  
  
    def getPartition(key: Any): Int =  
        parseDomain(key.toString).hashCode % numPartitions  
  
    def equals(other: Any): Boolean =  
        other.isInstanceOf[DomainPartitioner]  
}
```

Needed for Spark to tell when two partitioners are equivalent

Way to find out how an RDD is Partitioned

Use the `.partitioner` method on RDD

```
scala> val a = sc.parallelize(List((1, 1), (2, 2)))
scala> val b = sc.parallelize(List((1, 1), (2, 2)))
scala> val joined = a.join(b)
```

```
scala> a.partitionер
res0: Option[Partitioner] = None
```

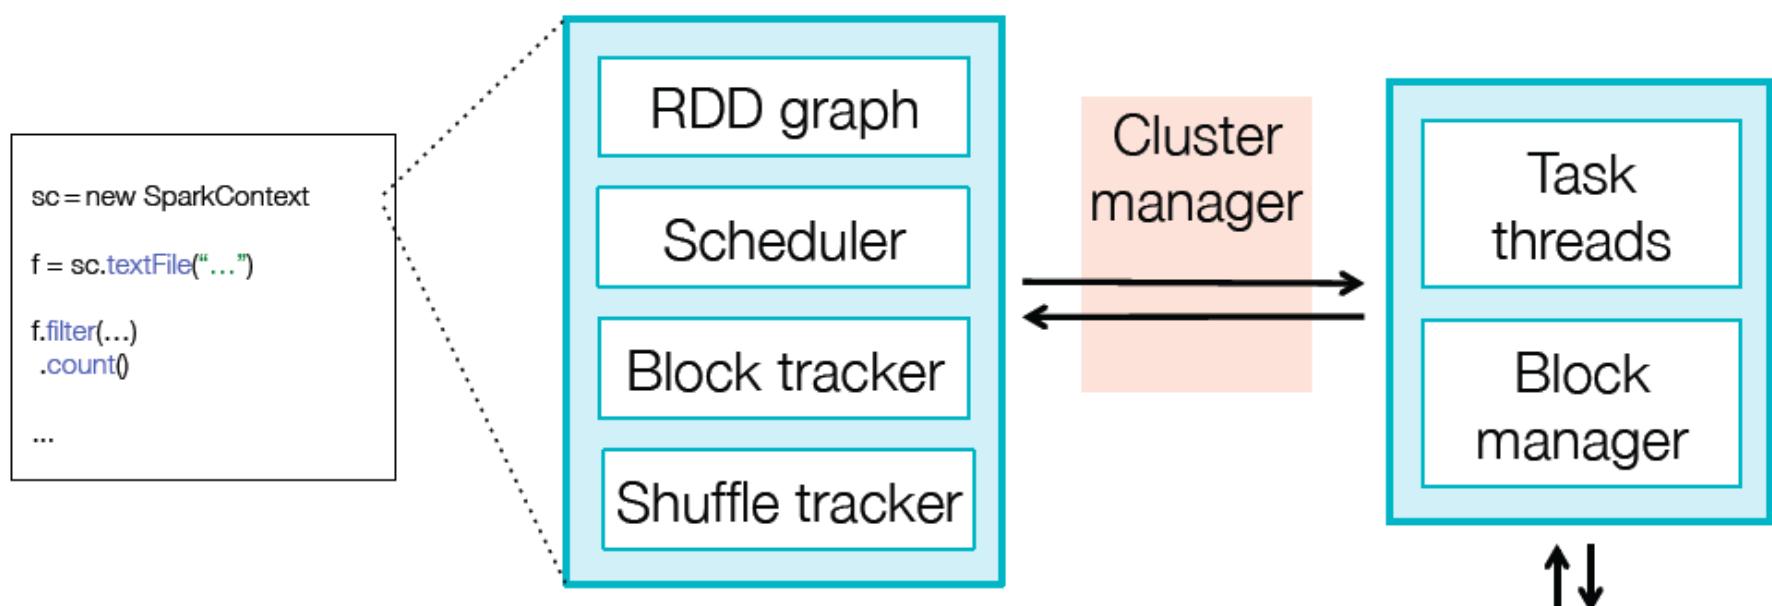

```
scala> joined.partitionер
res1: Option[Partitioner] = Some(HashPartitioner@286d41c0)
```

A Spark Application

Your program
(JVM / Python)

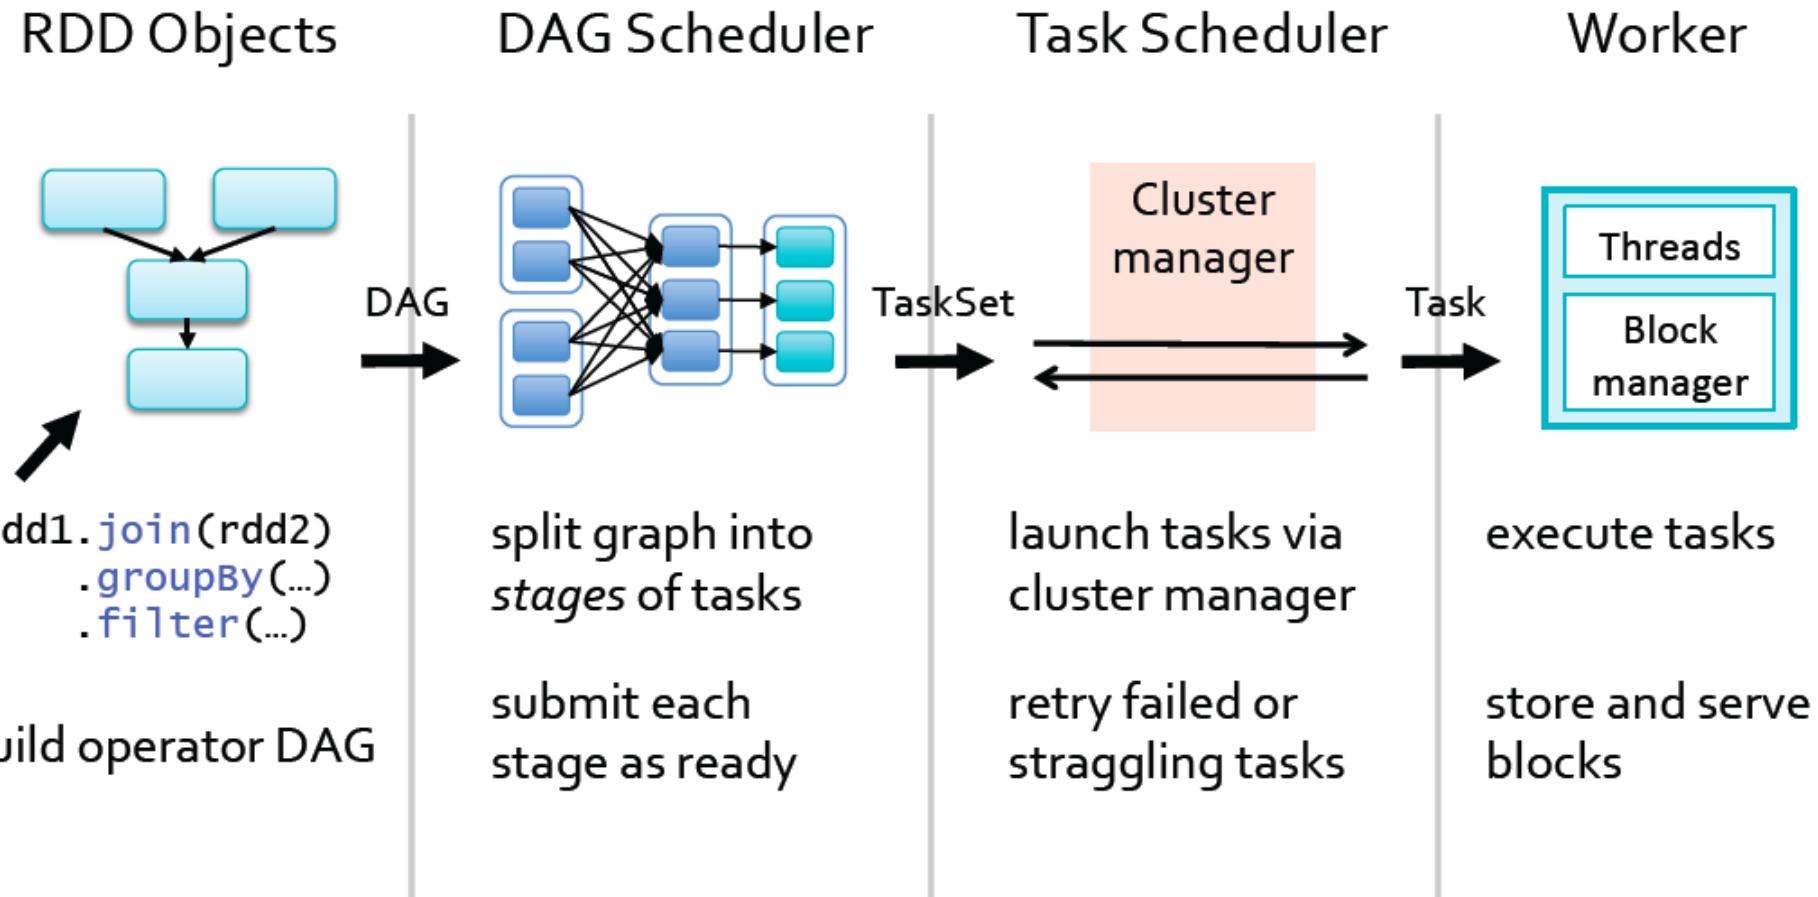

Spark driver
(app master)

Spark executor
(multiple of them)

A single application often contains multiple actions

Execution Process of Spark

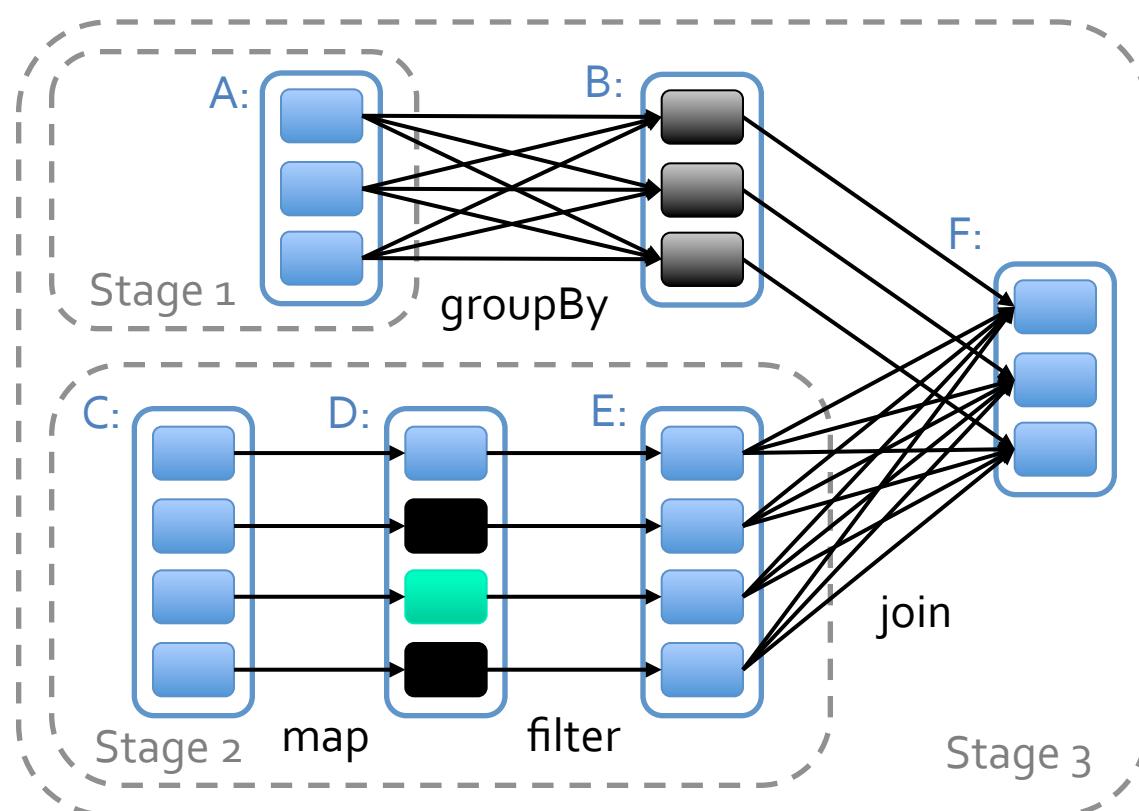

DAG Scheduler of Spark

- Input: RDD and Partitions to compute
- Output: Output from Actions of those Partitions
- Roles:
 - Build stages of tasks
 - Submit them to lower level scheduler, e.g. YARN or Mesos, Standalone) as ready
 - Lower level scheduler will schedule data based on locality
 - Resubmit failed stages if outputs are lost

Job Scheduler of Spark

- Captures RDD dependency graph
- Pipelines functions into “stages”
- Cache-aware for data reuse & locality
- Partitioning-aware to avoid shuffles

= RDD

= cached partition

Outline

- Introduction to Scala & functional programming
- What is Spark
- Resilient Distributed Datasets (RDDs)
- Implementation
- Conclusion

Codebase of Spark

Implement Spark Core in about 14,000 Lines of Scala:

Spark core: 14,000 LOC

RDD ops: 1600

Scheduler: 2000

Block store: 2000

Networking: 1200

Accumulators: 200

Broadcast: 3500

Interpreter:
3300 LOC

Hadoop I/O:
400 LOC

Mesos runner:
700 LOC

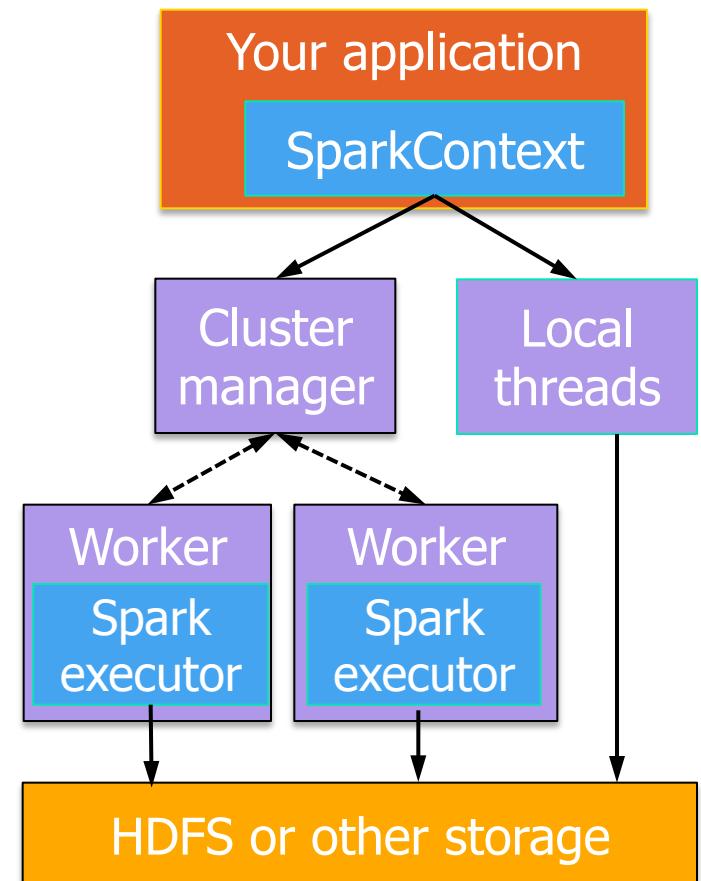

Standalone runner:
1200 LOC

Software Components: How to run Spark ?

- Spark runs as a library in your program (1 instance per app)
 - Runs tasks locally or on cluster
 - Mesos, YARN or standalone mode
- >> new **SparkContext** (masterUrl,
jobname, [sparkhome], [jars])

```
>> MASTER=local[n] ./spark-shell  
>> MASTER=HOST:PORT ./spark-shell
```

- Access storage systems via Hadoop InputFormat API
 - Can use HBase, HDFS, Tachyon, S3, Cassandra, ...

Add Spark to Your Project

- Scala / Java: add a Maven dependency on
 - groupId: org.spark-project
 - artifactId: spark-core_2.9.3
 - version: 0.7.3
- Python: run program with our pyspark script

Create a SparkContext

Scala

- `import spark.SparkContext`
- `import spark.SparkContext._`
- `val sc = new SparkContext("url", "name", "sparkHome", Seq("app.jar"))`

Cluster URL, or
local / local[N]

App name

Spark install
path on
cluster

List of JARs with
app code (to
ship)

```
import spark.api...
```

```
JavaSparkContext sc = new JavaSparkContext(  
    "masterUrl", "name", "sparkHome", new String[] {"app.jar"});
```

Java

Python

```
from pyspark import SparkContext
```

```
sc = SparkContext("masterUrl", "name", "sparkHome", ["library.py"]))
```

Getting Started

- Download Spark:

www.spark.apache.org/downloads.html

- Documentation and video tutorials:

www.spark.apache.org/docs/latest

- Other Resources:

www.Databricks.com

Local Execution

- Just pass local or local[k] as master URL
- Debug using local debuggers
 - For Java / Scala, just run your program in a debugger
 - For Python, use an attachable debugger (e.g. PyDev)
- Great for development & unit tests

Cluster Execution

- Easiest way to launch is EC2:

```
./spark-ec2 -k keypair -i id_rsa.pem -s slaves \
[launch|stop|start|destroy] clusterName
```

- Several options for private clusters:
 - Standalone mode (similar to Hadoop's deploy scripts)
 - Mesos
 - Hadoop YARN
- Amazon EMR: tinyurl.com/spark-emr

Key Distinctions for Spark vs. MapReduce

- generalized patterns
⇒ unified engine for many use cases
- lazy evaluation of the lineage graph
⇒ reduces wait states, better pipelining
- generational differences in hardware
⇒ off-heap use of large memory spaces
- functional programming / ease of use
⇒ reduction in cost to maintain large apps
- lower overhead for starting jobs
- less expensive shuffles

Conclusion

- Scala : OOP + FP
- RDDs: fault tolerance, data locality/ partitioning-control, scalability
- RDD implemented in Spark using Scala
- Spark offers a rich API to make data analytics *fast*: both fast to write and fast to run
 - Achieves 50 or even 100+ speedups in real applications
- Rapidly growing community
